#### IOMUXC\_SW\_MUX\_CTL\_PAD\_EPDC\_DATA06 field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4 SION	Software Input On Field.  Force the selected mux mode input path no matter of MUX_MODE functionality.  1 <b>ENABLED</b> — Force input path of pad EPDC_D6. 0 <b>DISABLED</b> — Input Path is determined by functionality of the selected mux mode (regular).
3 Reserved	This read-only field is reserved and always has the value 0.
2–0 MUX_MODE	MUX Mode Select Field.  Select 1 of 6 iomux modes to be used for pad: EPDC_D6.  NOTE: Pad EPDC_D6 is involved in Daisy Chain.  000 <b>ALT0</b> — Select signal EPDC_DATA06. 001 <b>ALT1</b> — Select signal ECSPI4_SS3. 010 <b>ALT2</b> — Select signal LCD_DATA30. 011 <b>ALT3</b> — Select signal CSI_DATA06.  - Configure register IOMUXC_CSI_CSI_DATA06_SELECT_INPUT for mode ALT3. 100 <b>ALT4</b> — Select signal SPDC_DATA06. 101 <b>ALT5</b> — Select signal GPIO1_IO13.

### 30.4.45 Pad Mux Register (IOMUXC\_SW\_MUX\_CTL\_PAD\_EPDC\_DATA07)

Address: 20E\_0000h base + C4h offset = 20E\_00C4h

#### IOMUXC\_SW\_MUX\_CTL\_PAD\_FEC\_CRSDV field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4 SION	Software Input On Field.  Force the selected mux mode input path no matter of MUX_MODE functionality.  1 <b>ENABLED</b> — Force input path of pad FEC_CRSDV. 0 <b>DISABLED</b> — Input Path is determined by functionality of the selected mux mode (regular).
3 Reserved	This read-only field is reserved and always has the value 0.
2–0 MUX_MODE	MUX Mode Select Field.  Select 1 of 7 iomux modes to be used for pad: FEC_CRSDV.  NOTE: Pad FEC_CRSDV is involved in Daisy Chain.  000 <b>ALT0</b> — Select signal FEC_RX_DV. - Configure register IOMUXC_FEC_FEC_RX_DV_SELECT_INPUT for mode ALT0. 001 <b>ALT1</b> — Select signal SD4_DATA1. - Configure register IOMUXC_USDHC4_DATA1_IN_SELECT_INPUT for mode ALT1. 010 <b>ALT2</b> — Select signal AUD6_TXC. - Configure register IOMUXC_AUD6_INPUT_TXCLK_AMX_SELECT_INPUT for mode ALT2. 011 <b>ALT3</b> — Select signal ECSPI4_MISO. - Configure register IOMUXC_ECSPI4_MISO_SELECT_INPUT for mode ALT3. 100 <b>ALT4</b> — Select signal GPT_COMPARE2. 101 <b>ALT5</b> — Select signal GPIO4_IO25. 110 <b>ALT6</b> — Select signal ARM_TRACE31.

### 30.4.71 Pad Mux Register (IOMUXC\_SW\_MUX\_CTL\_PAD\_FEC\_MDC)

Address: 20E\_0000h base + 12Ch offset = 20E\_012Ch

#### IOMUXC\_SW\_MUX\_CTL\_PAD\_LCD\_DATA21 field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4 SION	Software Input On Field.  Force the selected mux mode input path no matter of MUX_MODE functionality.  1 <b>ENABLED</b> — Force input path of pad LCD_DAT21. 0 <b>DISABLED</b> — Input Path is determined by functionality of the selected mux mode (regular).
3 Reserved	This read-only field is reserved and always has the value 0.
2–0 MUX_MODE	MUX Mode Select Field.  Select 1 of 8 iomux modes to be used for pad: LCD_DAT21.  NOTE: Pad LCD_DAT21 is involved in Daisy Chain.  000 <b>ALT0</b> — Select signal LCD_DATA21. - Configure register IOMUXC_LCD_DATA21_SELECT_INPUT for mode ALT0. 001 <b>ALT1</b> — Select signal KEY_ROW6. - Configure register IOMUXC_KEY_ROW6_SELECT_INPUT for mode ALT1. 010 <b>ALT2</b> — Select signal CSI_DATA12. - Configure register IOMUXC_CSI_CSI_DATA12_SELECT_INPUT for mode ALT2. 011 <b>ALT3</b> — Select signal EIM_DATA15. 100 <b>ALT4</b> — Select signal GPT_COMPARE2. 101 <b>ALT5</b> — Select signal GPIO3_IO09. 110 <b>ALT6</b> — Select signal ARM_TRACE21. 111 <b>ALT7</b> — Select signal SRC_BOOT_CFG29.

### 30.4.119 Pad Mux Register (IOMUXC\_SW\_MUX\_CTL\_PAD\_LCD\_DATA22)

Address: 20E\_0000h base + 1ECh offset = 20E\_01ECh

#### IOMUXC\_SW\_MUX\_CTL\_PAD\_SD1\_DATA6 field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4 SION	Software Input On Field.  Force the selected mux mode input path no matter of MUX_MODE functionality.  1 <b>ENABLED</b> — Force input path of pad SD1_DATA6. 0 <b>DISABLED</b> — Input Path is determined by functionality of the selected mux mode (regular).
3 Reserved	This read-only field is reserved and always has the value 0.
2–0 MUX_MODE	MUX Mode Select Field.  Select 1 of 6 iomux modes to be used for pad: SD1_DATA6.  NOTE: Pad SD1_DATA6 is involved in Daisy Chain.  000 <b>ALT0</b> — Select signal SD1_DATA6. 001 <b>ALT1</b> — Select signal FEC_TX_EN. 010 <b>ALT2</b> — Select signal KEY_COL4. - Configure register IOMUXC_KEY_COL4_SELECT_INPUT for mode ALT2. 011 <b>ALT3</b> — Select signal EPDC_SDOEZ. 100 <b>ALT4</b> — Select signal UART4_RTS_B. - Configure register IOMUXC_UART4_UART_RTS_B_SELECT_INPUT for mode ALT4. 101 <b>ALT5</b> — Select signal GPIO5_IO07.

### 30.4.144 Pad Mux Register (IOMUXC\_SW\_MUX\_CTL\_PAD\_SD1\_DATA7)

Address: 20E\_0000h base + 250h offset = 20E\_0250h

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4 SION	Software Input On Field.  Force the selected mux mode input path no matter of MUX_MODE functionality.  1 <b>ENABLED</b> — Force input path of pad SD2_RST. 0 <b>DISABLED</b> — Input Path is determined by functionality of the selected mux mode (regular).
3 Reserved	This read-only field is reserved and always has the value 0.
2–0 MUX_MODE	MUX Mode Select Field.  Select 1 of 6 iomux modes to be used for pad: SD2_RST.  000 <b>ALT0</b> — Select signal SD2_RESET. 001 <b>ALT1</b> — Select signal FEC_REF_OUT. 010 <b>ALT2</b> — Select signal WDOG2_B. 011 <b>ALT3</b> — Select signal SPDIF_OUT. 100 <b>ALT4</b> — Select signal CSI_MCLK. 101 <b>ALT5</b> — Select signal GPIO4_IO27.

### 30.4.156 Pad Mux Register (IOMUXC\_SW\_MUX\_CTL\_PAD\_SD3\_CLK)

Address: 20E\_0000h base + 280h offset = 20E\_0280h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												SION	0	MUX_MODE	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

#### IOMUXC\_SW\_MUX\_CTL\_PAD\_SD3\_CLK field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4 SION	Software Input On Field.  Force the selected mux mode input path no matter of MUX_MODE functionality.  1 <b>ENABLED</b> — Force input path of pad SD3_CLK. 0 <b>DISABLED</b> — Input Path is determined by functionality of the selected mux mode (regular).
3 Reserved	This read-only field is reserved and always has the value 0.
2–0 MUX_MODE	MUX Mode Select Field.  Select 1 of 7 iomux modes to be used for pad: SD3_CLK.  NOTE: Pad SD3_CLK is involved in Daisy Chain.  000 <b>ALT0</b> — Select signal SD3_CLK. 001 <b>ALT1</b> — Select signal AUD5_RXFS. - Configure register IOMUXC_AUD5_INPUT_RXFS_AMX_SELECT_INPUT for mode ALT1. 010 <b>ALT2</b> — Select signal KEY_COL5. - Configure register IOMUXC_KEY_COL5_SELECT_INPUT for mode ALT2. 011 <b>ALT3</b> — Select signal CSI_DATA10. - Configure register IOMUXC_CSI_CSI_DATA10_SELECT_INPUT for mode ALT3. 100 <b>ALT4</b> — Select signal WDOG1_RESET_B_DEB. 101 <b>ALT5</b> — Select signal GPIO5_IO18. 110 <b>ALT6</b> — Select signal USB_OTG1_PWR.

### 30.4.157 Pad Mux Register (IOMUXC\_SW\_MUX\_CTL\_PAD\_SD3\_CMD)

Address: 20E\_0000h base + 284h offset = 20E\_0284h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												0	MUX_MODE		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

#### IOMUXC\_SW\_MUX\_CTL\_PAD\_SD3\_CMD field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4 SION	Software Input On Field.  Force the selected mux mode input path no matter of MUX_MODE functionality.  1 <b>ENABLED</b> — Force input path of pad SD3_CMD. 0 <b>DISABLED</b> — Input Path is determined by functionality of the selected mux mode (regular).
3 Reserved	This read-only field is reserved and always has the value 0.
2–0 MUX_MODE	MUX Mode Select Field.  Select 1 of 7 iomux modes to be used for pad: SD3_CMD.  NOTE: Pad SD3_CMD is involved in Daisy Chain.  000 <b>ALT0</b> — Select signal SD3_CMD. 001 <b>ALT1</b> — Select signal AUD5_RXC. - Configure register IOMUXC_AUD5_INPUT_RXCLK_AMX_SELECT_INPUT for mode ALT1. 010 <b>ALT2</b> — Select signal KEY_ROW5. - Configure register IOMUXC_KEY_ROW5_SELECT_INPUT for mode ALT2. 011 <b>ALT3</b> — Select signal CSI_DATA11. - Configure register IOMUXC_CSI_CSI_DATA11_SELECT_INPUT for mode ALT3. 100 <b>ALT4</b> — Select signal USB_OTG2_ID. - Configure register IOMUXC_ANALOG_USB_H1_ID_SELECT_INPUT for mode ALT4. 101 <b>ALT5</b> — Select signal GPIO5_IO21. 110 <b>ALT6</b> — Select signal USB_OTG2_PWR.

### 30.4.158 Pad Mux Register (IOMUXC\_SW\_MUX\_CTL\_PAD\_SD3\_DATA0)

Address: 20E\_0000h base + 288h offset = 20E\_0288h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### IOMUXC\_SW\_PAD\_CTL\_PAD\_EPDC\_PWR\_CTRL0 field descriptions

Field	Description
31–23 Reserved	This read-only field is reserved and always has the value 0.
22 LVE	Low Voltage Enable Field Select one of next values for pad: EPDC_PWRCTRL0.  0 <b>DISABLED</b> — High Voltage 1 <b>ENABLED</b> — Low Voltage
21–17 Reserved	This read-only field is reserved and always has the value 0.
16 HYS	Hysteresis Enable Field Select one of next values for pad: EPDC_PWRCTRL0.  0 <b>DISABLED</b> — CMOS input 1 <b>ENABLED</b> — Schmitt trigger input
15–14 PUS	Pull Up / Down Config. Field Select one of next values for pad: EPDC_PWRCTRL0.  00 <b>100K_OHM_PD</b> — 100K Ohm Pull Down 01 <b>47K_OHM_PU</b> — 47K Ohm Pull Up 10 <b>100K_OHM_PU</b> — 100K Ohm Pull Up 11 <b>22K_OHM_PU</b> — 22K Ohm Pull Up
13 PUE	Pull / Keep Select Field Select one of next values for pad: EPDC_PWRCTRL0.  0 <b>KEEP</b> — Keeper Enabled 1 <b>PULL</b> — Pull Enabled
12 PKE	Pull / Keep Enable Field Select one of next values for pad: EPDC_PWRCTRL0.

Table continues on the next page...

## IOMUXC\_SW\_PAD\_CTL\_PAD\_EPDC\_PWR\_CTRL0 field descriptions (continued)

Field	Description
	0 <b>DISABLED</b> — Pull/Keeper Disabled 1 <b>ENABLED</b> — Pull/Keeper Enabled
11 ODE	Open Drain Enable Field Enables open drain of the pin.  0 <b>DISABLED</b> — Output is CMOS. 1 <b>ENABLED</b> — Output is Open Drain.
10–8 Reserved	This read-only field is reserved and always has the value 0.
7–6 SPEED	Speed Field Select one of next values for pad: EPDC_PWRCTRL0.  00 <b>RESERVED0</b> — Reserved 01 <b>50MHZ</b> — Low (50 MHz) 10 <b>100MHZ</b> — Medium (100 MHz) 11 <b>200MHZ</b> — Maximum (200 MHz)
5–3 DSE	Drive Strength Field Select one of next values for pad: EPDC_PWRCTRL0.  000 <b>HIZ</b> — HI-Z 001 <b>240_OHM</b> — 240 Ohm 010 <b>120_OHM</b> — 120 Ohm 011 <b>80_OHM</b> — 80 Ohm 100 <b>60_OHM</b> — 60 Ohm 101 <b>48_OHM</b> — 48 Ohm 110 <b>40_OHM</b> — 40 Ohm 111 <b>34_OHM</b> — 34 Ohm
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 SRE	Slew Rate Field Slew rate control.  0 <b>SLOW</b> — Slow Slew Rate 1 <b>FAST</b> — Fast Slew Rate

**IOMUXC\_SW\_PAD\_CTL\_PAD\_USB\_H\_STROBE field descriptions**

Field	Description
31–20 Reserved	This read-only field is reserved and always has the value 0.
19–18 DDR_SEL	DDR Select Field Select one of next values for pad: HSIC_STROBE.  00 <b>RESERVED0</b> — Reserved 01 <b>RESERVED1</b> — Reserved

*Table continues on the next page...*

**IOMUXC\_SW\_PAD\_CTL\_PAD\_USB\_H\_STROBE field descriptions (continued)**

Field	Description
	10 <b>1P2V_IO</b> — 1.2V I/O interfaces including USB HSIC. Provides calibrated drive strengths for signals ranging from 1.0V up to 1.3V. 11 <b>1P5V_IO</b> — 1.5V I/O interfaces. Provides calibrated drive strengths for signals ranging from 1.3V to 2.5V.
17 DDR_INPUT	DDR / CMOS Input Mode Field Select one of next values for pad: HSIC_STROBE. 0 <b>CMOS</b> — CMOS input mode. 1 <b>DIFFERENTIAL</b> — Differential input mode.
16 HYS	Hysteresis Enable Field Select one of next values for pad: HSIC_STROBE. 0 <b>DISABLED</b> — CMOS input 1 <b>ENABLED</b> — Schmitt trigger input
15–14 PUS	Pull Up / Down Config. Field Select one of next values for pad: HSIC_STROBE. 00 <b>100K_OHM_PD</b> — 100K Ohm Pull Down 01 <b>47K_OHM_PU</b> — 47K Ohm Pull Up 10 <b>100K_OHM_PU</b> — 100K Ohm Pull Up 11 <b>22K_OHM_PU</b> — 22K Ohm Pull Up
13 PUE	Pull / Keep Select Field Select one of next values for pad: HSIC_STROBE. 0 <b>KEEP</b> — Keeper Enabled 1 <b>PULL</b> — Pull Enabled
12 PKE	Pull / Keep Enable Field Select one of next values for pad: HSIC_STROBE. 0 <b>DISABLED</b> — Pull/Keeper Disabled 1 <b>ENABLED</b> — Pull/Keeper Enabled
11 Reserved	This read-only field is reserved and always has the value 0.
10–8 ODT	On Die Termination Field Read Only Field The value of this field is fixed and cannot be changed. 000 <b>DISABLED</b> — Disabled
7–6 Reserved	This read-only field is reserved and always has the value 0.
5–3 DSE	Drive Strength Field Select one of next values for pad: HSIC_STROBE. 000 <b>HIZ</b> — HI-Z 001 <b>240_OHM</b> — 240 Ohm

*Table continues on the next page...*

**IOMUXC\_SW\_PAD\_CTL\_PAD\_USB\_H\_STROBE field descriptions (continued)**

Field	Description
010 <b>120_OHM</b> — 120 Ohm 011 <b>80_OHM</b> — 80 Ohm 100 <b>60_OHM</b> — 60 Ohm 101 <b>48_OHM</b> — 48 Ohm 110 <b>40_OHM</b> — 40 Ohm 111 <b>34_OHM</b> — 34 Ohm	
2–0 Reserved	This read-only field is reserved and always has the value 0.

#### IOMUXC\_SW\_PAD\_CTL\_PAD\_JTAG\_TDO field descriptions

Field	Description
31–23 Reserved	This read-only field is reserved and always has the value 0.
22 LVE	Low Voltage Enable Field Read Only Field The value of this field is fixed and cannot be changed.  0 <b>DISABLED</b> — High Voltage
21–17 Reserved	This read-only field is reserved and always has the value 0.
16 HYS	Hysteresis Enable Field Read Only Field The value of this field is fixed and cannot be changed.  0 <b>DISABLED</b> — CMOS input
15–14 PUS	Pull Up / Down Config. Field Read Only Field The value of this field is fixed and cannot be changed.  10 <b>100K_OHM_PU</b> — 100K Ohm Pull Up
13 PUE	Pull / Keep Select Field Read Only Field The value of this field is fixed and cannot be changed.  0 <b>KEEP</b> — Keeper Enabled
12 PKE	Pull / Keep Enable Field Select one of next values for pad: JTAG_TDO.

*Table continues on the next page...*

**IOMUXC\_SW\_PAD\_CTL\_PAD\_JTAG\_TDO field descriptions (continued)**

Field	Description
	0 <b>DISABLED</b> — Pull/Keeper Disabled 1 <b>ENABLED</b> — Pull/Keeper Enabled
11 ODE	Open Drain Enable Field Enables open drain of the pin. Read Only Field The value of this field is fixed and cannot be changed. 0 <b>DISABLED</b> — Output is CMOS.
10–8 Reserved	This read-only field is reserved and always has the value 0.
7–6 SPEED	Speed Field Read Only Field The value of this field is fixed and cannot be changed. 10 <b>100MHZ</b> — Medium (100 MHz)
5–3 DSE	Drive Strength Field Read Only Field The value of this field is fixed and cannot be changed. 110 <b>40_OHM</b> — 40 Ohm
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 SRE	Slew Rate Field Slew rate control. Read Only Field The value of this field is fixed and cannot be changed. 1 <b>FAST</b> — Fast Slew Rate

### 30.4.279 Pad Control Register (IOMUXC\_SW\_PAD\_CTL\_PAD\_JTAG\_TMS)

Address: 20E\_0000h base + 46Ch offset = 20E\_046Ch

#### IOMUXC\_SW\_PAD\_CTL\_PAD\_LCD\_ENABLE field descriptions

Field	Description
31–23 Reserved	This read-only field is reserved and always has the value 0.
22 LVE	Low Voltage Enable Field Select one of next values for pad: LCD_ENABLE.  0 <b>DISABLED</b> — High Voltage 1 <b>ENABLED</b> — Low Voltage
21–17 Reserved	This read-only field is reserved and always has the value 0.
16 HYS	Hysteresis Enable Field Select one of next values for pad: LCD_ENABLE.  0 <b>DISABLED</b> — CMOS input 1 <b>ENABLED</b> — Schmitt trigger input
15–14 PUS	Pull Up / Down Config. Field Select one of next values for pad: LCD_ENABLE.  00 <b>100K_OHM_PD</b> — 100K Ohm Pull Down 01 <b>47K_OHM_PU</b> — 47K Ohm Pull Up 10 <b>100K_OHM_PU</b> — 100K Ohm Pull Up 11 <b>22K_OHM_PU</b> — 22K Ohm Pull Up
13 PUE	Pull / Keep Select Field Select one of next values for pad: LCD_ENABLE.  0 <b>KEEP</b> — Keeper Enabled 1 <b>PULL</b> — Pull Enabled
12 PKE	Pull / Keep Enable Field Select one of next values for pad: LCD_ENABLE.

Table continues on the next page...

**IOMUXC\_SW\_PAD\_CTL\_PAD\_LCD\_ENABLE field descriptions (continued)**

Field	Description
	0 <b>DISABLED</b> — Pull/Keeper Disabled 1 <b>ENABLED</b> — Pull/Keeper Enabled
11 ODE	Open Drain Enable Field Enables open drain of the pin.  0 <b>DISABLED</b> — Output is CMOS. 1 <b>ENABLED</b> — Output is Open Drain.
10–8 Reserved	This read-only field is reserved and always has the value 0.
7–6 SPEED	Speed Field Select one of next values for pad: LCD_ENABLE.  00 <b>RESERVED0</b> — Reserved 01 <b>50MHZ</b> — Low (50 MHz) 10 <b>100MHZ</b> — Medium (100 MHz) 11 <b>200MHZ</b> — Maximum (200 MHz)
5–3 DSE	Drive Strength Field Select one of next values for pad: LCD_ENABLE.  000 <b>HIZ</b> — HI-Z 001 <b>240_OHM</b> — 240 Ohm 010 <b>120_OHM</b> — 120 Ohm 011 <b>80_OHM</b> — 80 Ohm 100 <b>60_OHM</b> — 60 Ohm 101 <b>48_OHM</b> — 48 Ohm 110 <b>40_OHM</b> — 40 Ohm 111 <b>34_OHM</b> — 34 Ohm
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 SRE	Slew Rate Field Slew rate control.  0 <b>SLOW</b> — Slow Slew Rate 1 <b>FAST</b> — Fast Slew Rate

### 30.4.323 Pad Control Register (IOMUXC\_SW\_PAD\_CTL\_PAD\_LCD\_HSYNC)

Address: 20E\_0000h base + 51Ch offset = 20E\_051Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### IOMUXC\_UART5\_UART\_RTS\_B\_SELECT\_INPUT field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
2–0 DAISY	Input Select (DAISY) Field

Table continues on the next page...

**IOMUXC\_UART5\_UART\_RTS\_B\_SELECT\_INPUT field descriptions (continued)**

Field	Description
	Selecting Pads Involved in Daisy Chain.  Route RTS_B signal to pad when UART is in DCE mode. Route CTS_B signal to pad when UART is in DTE mode.
000	<b>ECSPI1_MISO_ALT2</b> — Selecting ALT2 mode of pad ECSPI1_MISO for UART5_RTS_B.
001	<b>ECSPI1_SS0_ALT2</b> — Selecting ALT2 mode of pad ECSPI1_SS0 for UART5_CTS_B.
010	<b>LCD_DATA12_ALT4</b> — Selecting ALT4 mode of pad LCD_DAT12 for UART5_RTS_B.
011	<b>LCD_DATA13_ALT4</b> — Selecting ALT4 mode of pad LCD_DAT13 for UART5_CTS_B.
100	<b>SD2_DATA0_ALT4</b> — Selecting ALT4 mode of pad SD2_DAT0 for UART5_RTS_B.
101	<b>SD2_DATA1_ALT4</b> — Selecting ALT4 mode of pad SD2_DAT1 for UART5_CTS_B.

### 30.4.509 Select Input Register (IOMUXC\_UART5\_UART\_RX\_DATA\_SELECT\_INPUT)

Address: 20E\_0000h base + 81Ch offset = 20E\_081Ch

## **Chapter 31**

# **Keypad Port (KPP)**

## 31.1 Overview

The Keypad Port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O).

The figure below shows the KPP block diagram. The KPP provides interface for the keypad matrix with 2-point contact or 3-point contact keys. The KPP is designed to simplify the software task of scanning a keypad matrix. With appropriate software support, the KPP is capable of detecting, debouncing, and decoding one or multiple keys pressed simultaneously on the keypad.

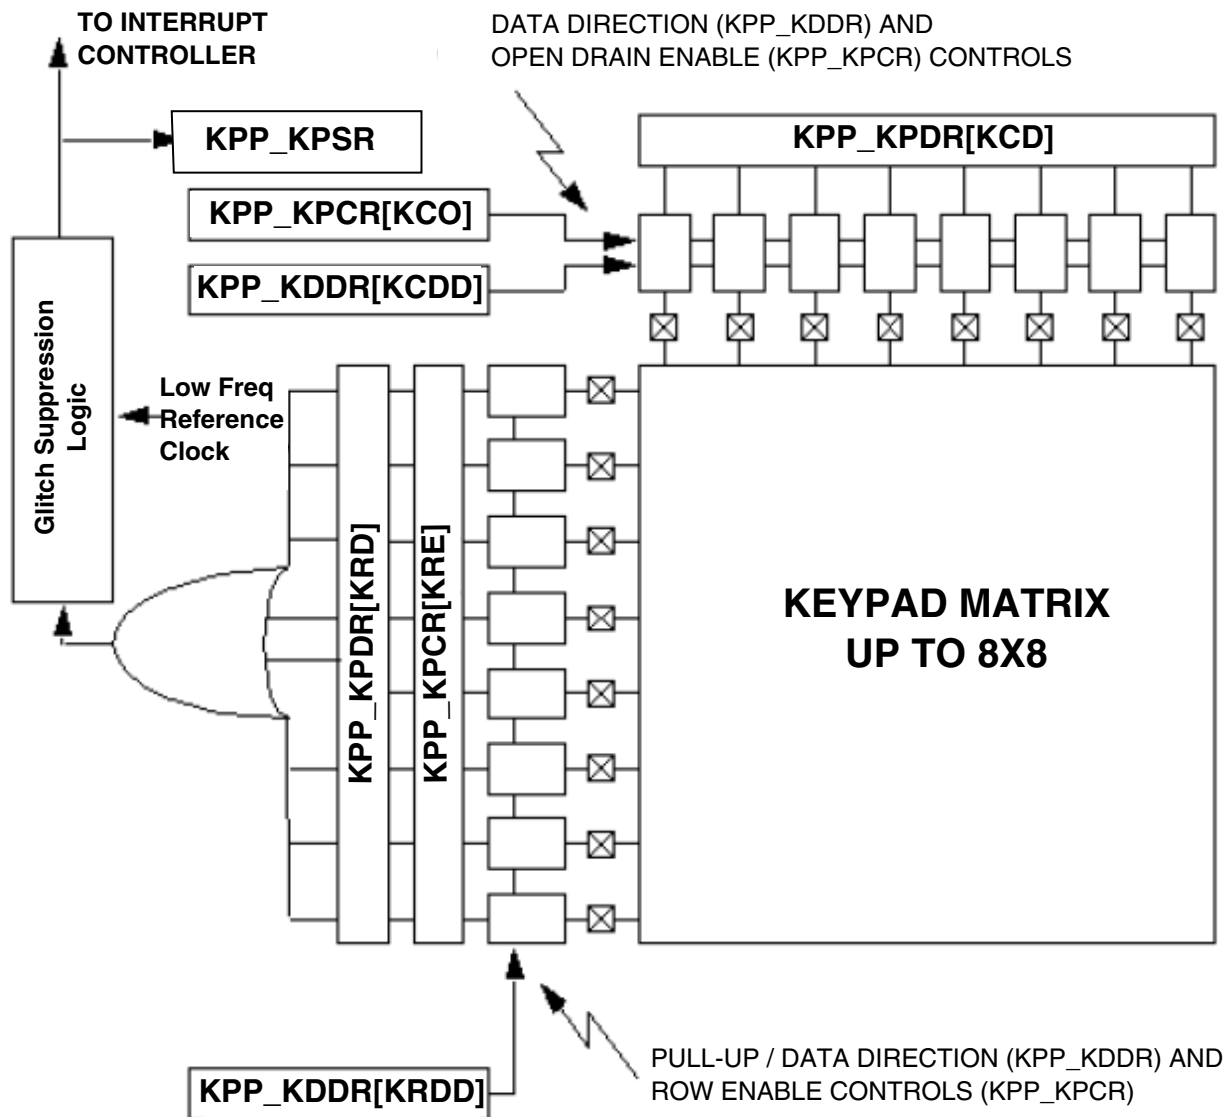

Figure 31-1. KPP Peripheral Block Diagram

### 31.1.1 Features

The KPP includes these distinctive features:

- Supports up to an 8 x 8 external key pad matrix
- Port pins can be used as general purpose I/O
- Open drain design
- Glitch suppression circuit design
- Multiple-key detection
- Long key-press detection
- Standby key-press detection
- Synchronizer chain clear
- Supports a 2-point and 3-point contact key matrix

### 31.1.2 Modes and Operations

This block supports the following modes:

- Run Mode-This is the normal functional mode in which the KPP can detect any key press event.
- Low Power Mode-The keypad can detect any key press even in low power modes (when there is no MCU clock).

## 31.2 Clocks

The table found here describes the clock sources for KPP.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 31-1. KPP Clocks**

Clock name	Clock Root	Description
ipg_clk_32k	ckil_sync_clk_root	Low-frequency reference clock (32kHz)
ipg_clk_s	ipg_clk_root	Peripheral access clock

## 31.3 External Signals

There are several pins dedicated to the KPP. Keypads of any configuration up to eight rows and eight columns are supported through the software configuration of the peripheral pins. Any pins not used for the keypad are available as general purpose I/O. The registers are configured such that the pins can be treated as an I/O port up to 16 bits wide.

See the table below for the list of external signals.

**Table 31-2. KPP External Signals**

Signal	Description	Pad	Mode	Direction
KEY_COL0	Column input or output pin, from chip	KEY_COL0	ALT0	I/O
		LCD_DAT8	ALT1	
		SD1_CLK	ALT2	
KEY_COL1	Column input or output pin, from chip	KEY_COL1	ALT0	I/O
		LCD_DAT10	ALT1	
		SD1_DAT0	ALT2	
KEY_COL2	Column input or output pin, from chip	KEY_COL2	ALT0	I/O
		LCD_DAT12	ALT1

		LCD_DAT21	ALT1	
		SD3_DAT1	ALT2	
KEY_ROW7	Row input or output pin, from chip	KEY_ROW7	ALT0	I/O
		LCD_DAT23	ALT1	
		SD3_DAT3	ALT2	

### 31.3.1 Input Pins

Any of the 16 pins associated with the KPP can be configured as inputs by writing a "0" to the appropriate bits in the KPP\_KDDR. Additionally, the least significant 8 bits (ROW inputs) corresponding to KPP\_KDDR[KRDD] have internal pull-ups, which are enabled when the pin is used as an input.

### 31.3.2 Output Pins

Any of the 16 pins associated with the KPP can be configured as outputs by writing the appropriate bits in the KPP\_KDDR to a "1". Additionally, the 8 most significant bits (15-8) can be designated as open drain outputs by writing a "1" to the appropriate bits in the KPP\_KPCR. The lower 8 bits (7-0) are always in "totem pole" style, driven when configured as outputs.

See the table below.

**Table 31-3. Keypad Port Column Modes**

KPP_KDDR (15:8)	KPP_KPCR (15:8)	Pin Function
0	x	Input
1	0	Totem-Pole Output
1	1	Open-Drain Output

### NOTE

Totem pole capability should be provided for column pins. Totem pole configuration helps for a faster discharge of keypad capacitance when all columns need to be quickly brought to a "1" during the scan routine. With this configuration, delay between the scanning of two subsequent columns is reduced.

### 31.3.3 Generation of Transfer Error Signal on Peripheral Bus

If there is an access to an address which is not implemented, then the KPP asserts a transfer error signal on Peripheral Bus.

## 31.4 Functional Description

The Keypad Port (KPP) is designed to simplify the software task of scanning a keypad matrix. With appropriate software support and matrix organization, the KPP is capable of detecting, debouncing, and decoding one or more keys pressed simultaneously on the keypad.

Logic in the KPP is capable of detecting a key press even while the processor is in one of the low power standby modes provided that a low frequency reference clock is on. The KPP may generate an ARM platform interrupt any time a key press or key release is detected. This interrupt is capable of forcing the processor out of a low power mode.

### 31.4.1 Keypad Matrix Construction

The KPP is designed to interface to a keypad matrix, which shorts the intersecting row and column lines together whenever a key is depressed. The interface is not optimized for any other switch configuration.

### 31.4.2 Keypad Port Configuration

The software must initialize the KPP for the size of the keypad matrix. Pins connected to the keypad columns should be configured as open-drain outputs. Pins connected to the keypad rows should be configured as inputs. On-chip, pull-up resistors should be implemented for active keypad rows.

In addition to enabled row inputs in the Keypad Control register, corresponding interrupt (depress or/and release) must also be enabled to generate an interrupt.

Discrete switches that are not part of the matrix may be connected to any unused row inputs. The second terminal of the discrete switch is connected to ground. The hardware detects closures of these switches without the need for software polling.

### 31.4.3 Keypad Matrix Scanning

Keypad scanning is performed by a software loop that walks a zero across each of the keypad columns, reading the value on the rows at each step. The process is repeated several times in succession, with the results of each pass optionally compared to those from the previous pass. When several (3 or 4) consecutive scans yield the same key closures, a valid key press has been detected. Software then can decode exactly which switch was depressed and pass the value up to the next higher software layer.

The basic debouncing period, which must be defined in the software routine, may be controlled with an internal timer. The basic period is the period between the scan of two consecutive columns, so the debouncing time between two consecutive scans of the whole matrix shall be the number of columns multiplied by the basic period.

### 31.4.4 Keypad Standby

There is no need for the ARM platform to continually scan the keypad. Between key presses, the keypad can be left in a state that requires no software intervention until the next key press is detected. To place the keypad in a standby state, software should write all column outputs low. Row inputs are left enabled. At this point, the ARM platform can attend to other tasks or revert to a low power standby mode. The KPP will interrupt the ARM platform if any key is pressed.

## Functional Description

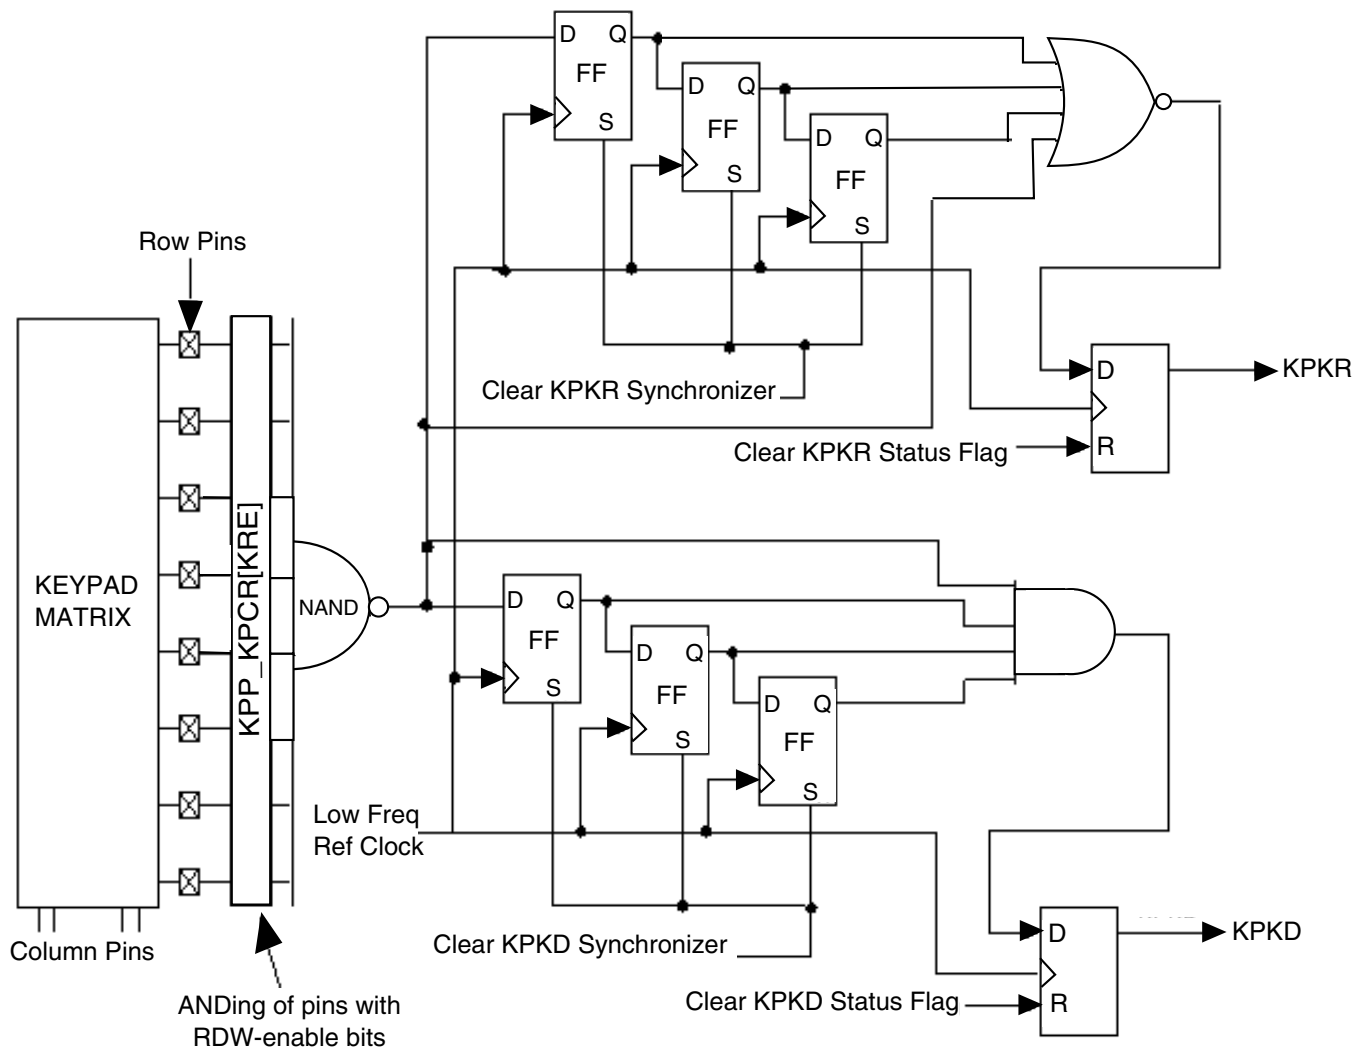

Upon receiving a keypad interrupt, the ARM platform should set all the column strobes high, and begin a normal keypad scanning routine to determine which key was pressed. It is important that open-drain drivers be used when scanning to prevent a possible DC path between power and ground through two or more switches.

### 31.4.5 Glitch Suppression on Keypad Inputs

A glitch suppression circuit qualifies the keypad inputs to prevent noise from inadvertently interrupting the ARM platform. The circuit is a 4-state synchronizer clocked from a low frequency reference clock source.

This clock must continue to run in any low power mode where the keypad is a wake-up source, as the ARM platform interrupt is generated from the synchronized input. An interrupt is not generated until all four synchronizer stages have latched a valid key assertion. This guarantees the filtering out of any noise less than three clock periods in duration of a low frequency reference clock. Noise filtering of the duration between three to four clock periods cannot be guaranteed. The interrupt output is latched in an S-R latch and remains asserted until cleared by the software. The Set input of the latch is rising-edge clocked. See the figure below.

**Figure 31-2. Keypad Synchronizer Functional Diagram**

### 31.4.6 Multiple Key Closures

Using the key press and Key release interrupts, the software can detect multiple keys or achieve n key rollover. The key scanning routine can be programmed accordingly.

See the following figures for illustrations of the interfacing of a 2-contact keypad matrix with the KPP controller. With proper enabling of row lines and the performing scan-routine, multiple key presses can be detected. When keys present on the same row are pressed, corresponding row lines (multiple lines) become low when the column is driven low during a scan-routine. By reading the data-register, pressed keys can be detected. Similarly, when keys present on same row line are pressed, the corresponding row line (only one line) becomes low when logic "0" is driven on the column line during a scan-routine.

**Figure 31-3. Multiple Key Presses on Same Column Line (Simplified View)**

**Figure 31-4. Multiple Key Presses on Same Row Line (Simplified View)**

#### NOTE

An n key rollover is a technique with which the system can recognize the order in which keys are pressed.

### 31.4.6.1 Ghost Key Problem and Correction

The KPP detects if one or multiple keys are pressed or released. In the case where a simple keypad matrix with two-contact switches is used, there is a chance of "ghost" key detection when three or more keys are pressed. This is a limitation imposed by such a keypad matrix.

As can be seen in [Figure 31-5](#), three keys pressed simultaneously can cause a short between the column currently "scanned" by the software and another column. Depending on the location of the third key pressed, a "ghost" key press may be detected.

However, this can be corrected by using a keypad matrix that provides "ghost" key protection. Such a matrix implements a one-way "diode" at all keypad points between rows and columns. This way, the multiple pressing of three keys will not cause a short at a fourth key (see [Figure 31-6](#)).

**Figure 31-5. Decoding Wrong Three- Key-Presses**

**Figure 31-6. Matrix with "Ghost" Key Protections**

### 31.4.7 3-Point Contact Keys Support

The KPP supports interfacing to a matrix consisting of 3-point contact keys. As shown in [Figure 31-7](#), two points of such a key are connected to keypad lines, while a third point is connected to ground (low logic).

The keypad lines should be configured as input and a pull-up should be present on these lines. When such a key is pressed, corresponding keypad lines go low and an interrupt is generated. There is no need to perform a scanning routine for identification of pressed key as it can be done by reading the keypad data-register. A limitation with such a matrix is that for every key at least one keypad row line should be used.

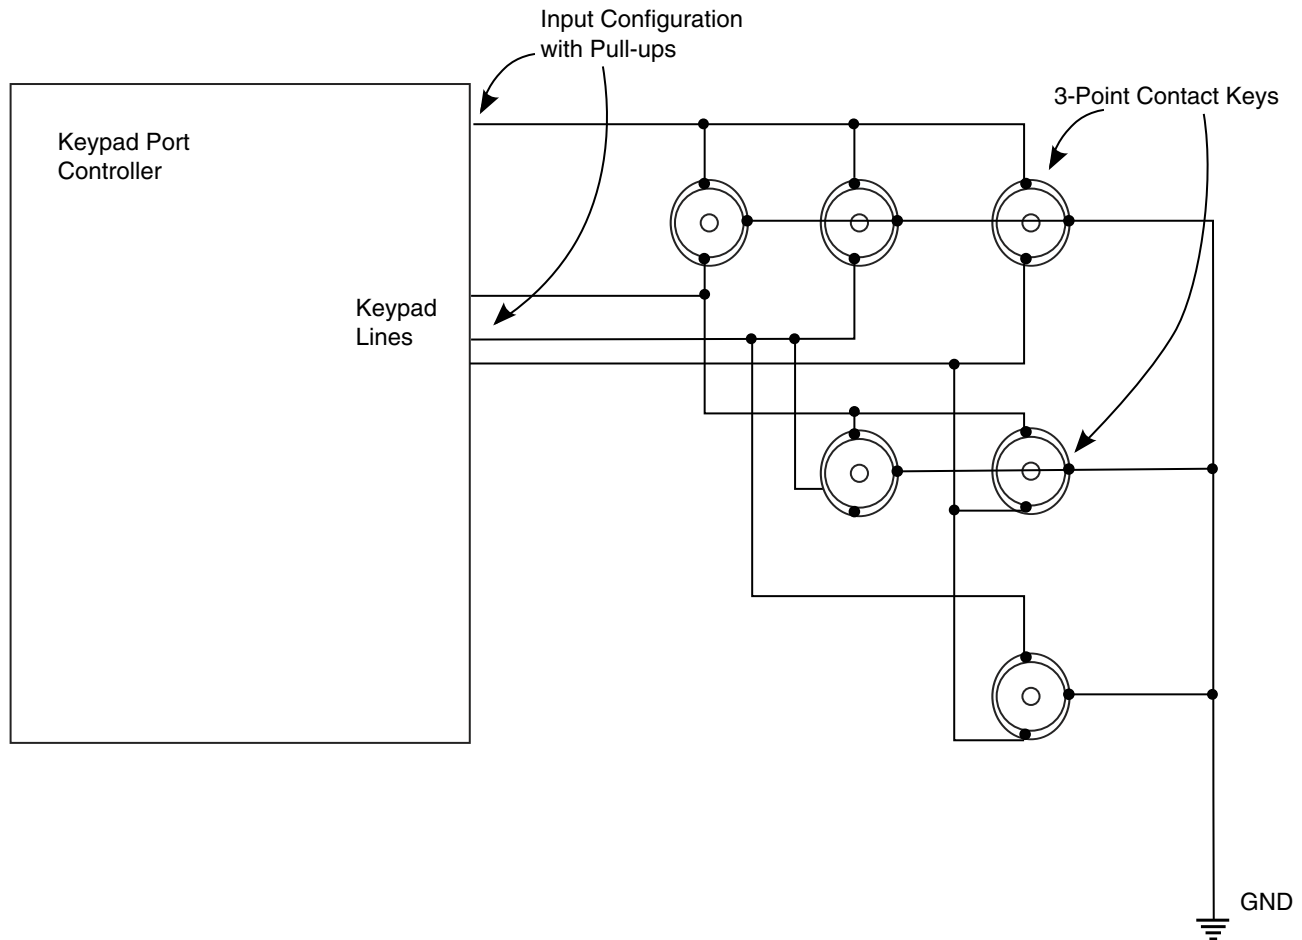

Figure 31-7. KPP Interface with 3-point Contact Key Matrix (Simplified View)

## 31.5 Initialization/Application Information

### 31.5.1 Typical Keypad Configuration and Scanning Sequence

Perform the following steps to configure the keypad:

1. Enable the number of rows in the keypad (KPP\_KPCR[KRE]).
2. Write 0s to KPP\_KPDR[KCD].
3. Configure the keypad columns as open-drain (KPP\_KPCR[KCO]).
4. Configure columns as output (KPP\_KDDR[KCDD]) and rows as input (KPP\_KDDR[KRDD]).
5. Clear the KPKD Status Flag and Synchronizer chain.
6. Set the KDIE control bit, and clear the KRIE control bit (avoid false release events).
7. (The system is now in standby mode, and awaiting a key press.)

### 31.5.2 Key Press Interrupt Scanning Sequence

Perform the following steps to perform a keypad scanning routine:

1. Disable both (depress and release) keypad interrupts.
2. Write 1s to KPP\_KPDR[KCD], setting column data to 1s.
3. Configure columns as totem pole outputs (for quick discharging of keypad capacitance).
4. Configure columns as open-drain.
5. Write a single column to 0, and other columns to 1.
6. Sample row inputs and save data. Multiple key presses can be detected on a single column.
7. Repeat Steps 2-6 for remaining columns.
8. Return all columns to 0 in preparation for standby mode.
9. Clear KPKD and KPKR status bit(s) by writing to a "1"; set the KPKR synchronizer chain by writing a "1" to the KPP\_KRSS register; and clear the KPKD synchronizer chain by writing a "1" to the KDSC register.
10. Re-enable the appropriate keypad interrupt(s) so that the KDIE detects a key hold condition, or the KRIE detects a key-release event.

### 31.5.3 Additional Comments

The order of key press detection can be done in software only. Therefore, the software may need to run the scan routines at very short intervals of time per the application's demands. The reason that such functionality cannot be put in the KPP is that the block is limited by the number of external pins.

For the keys that require a very precise order (such as game keys), individual GPIO pins may be more useful.

## 31.6 KPP Memory Map/Register Definition

The KPP contains four registers.

**KPP memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
20B_8000	Keypad Control Register (KPP_KPCR)	16	R/W	0000h	<a href="#">31.6.1/1989</a>
20B_8002	Keypad Status Register (KPP_KPSR)	16	R/W	0400h	<a href="#">31.6.2/1990</a>
20B_8004	Keypad Data Direction Register (KPP_KDDR)	16	R/W	0000h	<a href="#">31.6.3/1992</a>
20B_8006	Keypad Data Register (KPP_KPDR)	16	R/W	0000h	<a href="#">31.6.4/1992</a>

### 31.6.1 Keypad Control Register (KPP\_KPCR)

The Keypad Control Register determines which of the eight possible column strobes are to be open drain when configured as outputs, and which of the eight row sense lines are considered in generating an interrupt to the core.

It is up to the programmer to ensure that pins being used for functions other than the keypad are properly disabled. The KPP\_KPCR register is byte- or half-word-addressable.

Address: 20B\_8000h base + 0h offset = 20B\_8000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	KCO								KRE							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**KPP\_KPCR field descriptions**

Field	Description
15–8 KCO	Keypad Column Strobe Open-Drain Enable. Setting a column open-drain enable bit (KCO7-KCO0) disables the pull-up driver on that pin. Clearing the bit allows the pin to drive to the high state. This bit has no effect when the pin is configured as an input.  <b>NOTE:</b> Configuration of external port control logic (for example, IOMUX) should be done properly so that the KPP controls an open-drain enable of the pin.  0 <b>TOTEM_POLE</b> — Column strobe output is totem pole drive. 1 <b>OPEN_DRAIN</b> — Column strobe output is open drain.

*Table continues on the next page...*

**KPP\_KPCR field descriptions (continued)**

Field	Description
7–0 KRE	Keypad Row Enable. Setting a row enable control bit in this register enables the corresponding row line to participate in interrupt generation. Likewise, clearing a bit disables that row from being used to generate an interrupt. This register is cleared by a reset, disabling all rows. The row-enable logic is independent of the programmed direction of the pin. Writing a "0" to the data register of the pins configured as outputs will cause a keypad interrupt to be generated if the row enable associated with that bit is set.  0 Row is not included in the keypad key press detect. 1 Row is included in the keypad key press detect.

**31.6.2 Keypad Status Register (KPP\_KPSR)**

The Keypad Status Register reflects the state of the key press detect circuit. The KPP\_KPSR register is byte- or half-word-addressable.

Address: 20B\_8000h base + 2h offset = 20B\_8002h

Bit	15	14	13	12	11	10	9	8
Read	0						KRIE	KDIE
Write								
Reset	0	0	0	0	0	1	0	0
Bit	7	6	5	4	3	2	1	0
Read	0				0	0	KPKR	KPKD
Write					KRSS	KDSC	w1c	w1c
Reset	0	0	0	0	0	0	0	0

**KPP\_KPSR field descriptions**

Field	Description
15–10 Reserved	This read-only field is reserved and always has the value 0.
9 KRIE	Keypad Release Interrupt Enable. The software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain.  0 No interrupt request is generated when KPKR is set. 1 An interrupt request is generated when KPKR is set.
8 KDIE	Keypad Key Depress Interrupt Enable. Software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice-versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain.

*Table continues on the next page...*

**KPP\_KPSR field descriptions (continued)**

<b>Field</b>	<b>Description</b>
	<p>0 No interrupt request is generated when KPKD is set.</p> <p>1 An interrupt request is generated when KPKD is set.</p>
7–4 Reserved	This read-only field is reserved and always has the value 0.
3 KRSS	<p>Key Release Synchronizer Set. Self-clear bit. The Key release synchronizer is set by writing a logic one into this bit.</p> <p>Reads return a value of "0".</p> <p>0 No effect</p> <p>1 Set bits which sets keypad release synchronizer chain</p>
2 KDSC	<p>Key Depress Synchronizer Clear. Self-clear bit. The Key depress synchronizer is cleared by writing a logic "1" into this bit.</p> <p>Reads return a value of "0".</p> <p>0 No effect</p> <p>1 Set bits that clear the keypad depress synchronizer chain</p>
1 KPKR	<p>Keypad Key Release. The keypad key release (KPKR) status bit is set when all enabled rows are detected high after synchronization (the KPKR status bit will be set when cleared by a reset). The KPKR bit may be used to generate a maskable key release interrupt. The key release synchronizer may be set high by software after scanning the keypad to ensure a known state. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by software prior to the system exiting the state it represents.</p> <p>Reset value of register is "0" as long as reset is asserted. However when reset is de-asserted, the value of the register depends upon the external row pins and can become "1".</p> <p>0 No key release detected</p> <p>1 All keys have been released</p>
0 KPKD	<p>Keypad Key Depress. The keypad key depress (KPKD) status bit is set when one or more enabled rows are detected low after synchronization. The KPKD status bit remains set until cleared by the software. The KPKD bit may be used to generate a maskable key depress interrupt. If desired, the software may clear the key press synchronizer chain to allow a repeated interrupt to be generated while a key remains pressed. In this case, a new interrupt will be generated after the synchronizer delay (4 cycles of the low frequency reference clock elapses if a key remains pressed. This functionality can be used to detect a long key press. This allows detection of additional key presses of the same key or other keys.</p> <p>Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by the software prior to the system exiting the state it represents.</p> <p>0 No key presses detected</p> <p>1 A key has been depressed</p>

### 31.6.3 Keypad Data Direction Register (KPP\_KDDR)

The bits in the KPP\_KDDR control the direction of the keypad port pins. The upper eight bits in the register affect the pins designated as column strobes, while the lower eight bits affect the row sense pins. Setting any bit in this register configures the corresponding pin as an output. Clearing any bit in this register configures the corresponding port pin as an input. For the Keypad Row DDR, an internal pull-up is enabled if the corresponding bit is clear. This register is cleared by a reset, configuring all pins as inputs. The KPP\_KDDR register is byte- or half-word addressable.

#### NOTE

When a pin is used as row pin for keypad purposes, all corresponding pull-ups should be enabled at the upper level (for example, IOMUX) when the bit in KRDD is cleared.

Address: 20B\_8000h base + 4h offset = 20B\_8004h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	KCDD								KRDD							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### KPP\_KDDR field descriptions

Field	Description
15–8 KCDD	Keypad Column Data Direction Register. Setting a bit configures the corresponding COL $n$ pin as an output (where $n = 7$ through 0).  0 <b>INPUT</b> — COL $n$ pin is configured as an input. 1 <b>OUTPUT</b> — COL $n$ pin is configured as an output.
7–0 KRDD	Keypad Row Data Direction. Setting a bit configures the corresponding ROW $n$ pin as an output (where $n = 7$ through 0).  0 <b>INPUT</b> — ROW $n$ pin configured as an input. 1 <b>OUTPUT</b> — ROW $n$ pin configured as an output.

### 31.6.4 Keypad Data Register (KPP\_KPDR)

This 16-bit register is used to access the column and row data. Data written to this register is stored in an internal latch, and for each pin configured as an output, the stored data is driven onto the pin. A read of this register returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register.

The KPP\_KPDR register is byte- or half-word addressable. This register is not initialized by a reset. Valid data should be written to this register before any bits are configured as outputs.

Address: 20B\_8000h base + 6h offset = 20B\_8006h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	KCD								KRD							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### KPP\_KPDR field descriptions

Field	Description
15–8 KCD	Keypad Column Data. A read of these bits returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register. 0 Read/Write "0" from/to column ports 1 Read/Write "1" from/to column ports
7–0 KRD	Keypad Row Data. A read of these bits returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register. 0 Read/Write "0" from/to row ports 1 Read/Write "1" from/to row ports

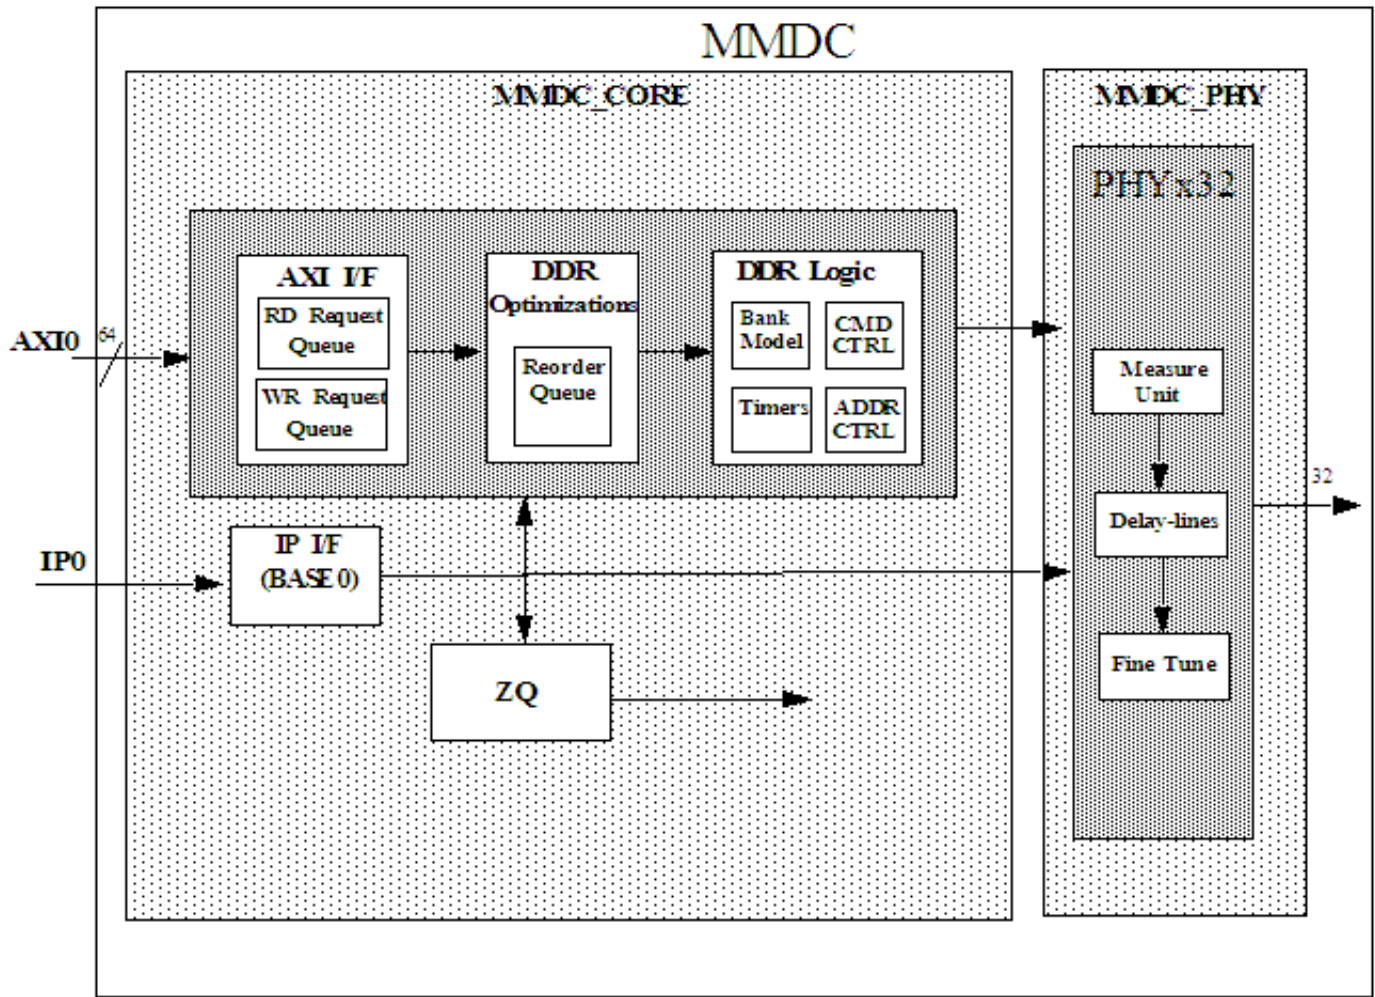

## Chapter 32

# Multi Mode DDR Controller (MMDC)

### 32.1 Overview

MMDC is a multi-mode DDR controller that supports DDR3/DDR3L x16/x32 and LPDDR2 x16/x32 memory types. MMDC is configurable, high performance, and optimized.

The following figure shows the MMDC block diagram.

**Figure 32-1. MMDC block diagram**

MMDC consists of a core (MMDC\_CORE) and PHY (MMDC\_PHY).

- The core is responsible for communication with the system through an AXI interface, DDR command generation, DDR command optimizations, and a read/write data path.
- The PHY is responsible for the timing adjustment; it uses special calibration mechanisms to ensure data capture margin at a clock rate of up to 400 MHz.

The internal memory map(configuration registers) of the MMDC can be configured through an IP channel (IPO). .

### 32.1.1 MMDC feature summary

The table found here summarizes the MMDC features.

**Table 32-1. MMDC feature summary**

Feature	Details
DDR standards	<ul style="list-style-type: none"> <li>• LV-DDR3, DDR3 x16, x32</li> <li>• LPDDR2 x16, x32</li> <li>• Does not support LPDDR1MDDR or DDR2</li> </ul>
DDR interface	<ul style="list-style-type: none"> <li>• x16, x32 data bus width</li> <li>• Density per DDR device of 256 Mbits–8 Gbits with the following column and row combinations: <ul style="list-style-type: none"> <li>• Column size of 8–12 bits</li> <li>• Row size of 11–16 bits</li> </ul> </li> <li>• Two chip selects</li> <li>• Up to 4 Gbytes of address space with configurable partitioning between CS0 and CS1</li> <li>• Supports burst length of 8 (aligned) for DDR3</li> <li>• Supports burst length of 4 for LPDDR2</li> </ul>
DDR performance	<ul style="list-style-type: none"> <li>• MMDC running at up to 400 MHz (800MT/s), see CCM block for actual clock frequencies supported.</li> <li>• Supports Real-Time priority by means of QoS sideband priority signals from the chip to enable various priority levels in the re-ordering mechanism: real-time, latency sensitive, normal priority.</li> <li>• Page hit/page miss optimizations</li> <li>• Consecutive read/write access optimizations</li> <li>• Supports deep read and write request queues to enable bank prediction.</li> <li>• Drives back the critical word in a read transaction as soon as it is received by the DDR device (does not wait until the whole data phase has been completed).</li> <li>• Keeps tracking of open memory pages</li> <li>• Supports bank interleaving</li> <li>• Special optimization in case of non-aligned wrap accesses in DDR3 mode (burst length 8)</li> </ul> <p><b>NOTE:</b> Due to reordering and optimization mechanisms (per different AXI Identifier (ID)), the transactions towards the DDR device may be driven in a different ID order than was received by the AXI master. In a similar fashion, the write response, read response or read data may be driven to the AXI master in a different ID order.</p>

*Table continues on the next page...*

**Table 32-1. MMDC feature summary (continued)**

Feature	Details
AXI interface	<ul style="list-style-type: none"> <li>• AXI bus compliant</li> <li>• Supports bus transfers of 8, 16, 32, 64 bits (single accesses and bursts) running at 400 MHz.</li> <li>• Supports AXI bursts length of up to 16</li> <li>• Supports burst types of WRAP, INCR and FIXED</li> <li>• Supports 16 bits AXI ID</li> <li>• Write data interleave depth is 1 (no support for Write Data Interleave)</li> <li>• Supports write data before address</li> <li>• Supports buffered/non-buffered accesses (AWCACHE[0] = 0b means a non-bufferable access and AWCACHE[0] = 1b means a bufferable access). The rest of the CACHE options are not supported               <ul style="list-style-type: none"> <li>• To keep data access coherency between write and read access of the same master, the response signal is sent as follows:                   <ul style="list-style-type: none"> <li>• Bufferable write access—BRESP will be sent when last data of the access has entered the MMDC.</li> <li>• Non-bufferable write access—BRESP will be sent when the data was physically written into the external memory device.</li> </ul> </li> </ul> </li> <li>• Supports four exclusive monitors per configurable ID for only a single access with a size of up to 64 bits</li> <li>• Supports AXI responses as follows:               <ul style="list-style-type: none"> <li>• Okay in case the access has been successful or exclusive access failure</li> <li>• Slave error in case of security violation</li> <li>• Exclusive okay in case the read or the write portion of an exclusive access has been successful</li> </ul> </li> </ul>
DDR calibration and delay-lines.	<ul style="list-style-type: none"> <li>• Supports various calibration processes which can be performed either automatically (hardware) or manually (software) towards either CS0 or CS1. (At the end of the process the delay-lines will work with one set of results.) The following calibration processes are supported:               <ul style="list-style-type: none"> <li>• ZQ calibration for external DDR device (in DDR3 through ZQ calibration command and in LPDDR2 through MRW command)                   <ul style="list-style-type: none"> <li>• Can be handled automatically for ZQ Short (periodically) and ZQ Long (at exit from self-refresh)</li> <li>• Can be handled manually at ZQ INIT</li> </ul> </li> <li>• ZQ calibration for i.MX DDR I/O pads for calibrating the DDR driving strength                   <ul style="list-style-type: none"> <li>• The sequence can be handled automatically by hardware</li> <li>• The sequence can be handled step by step manually by software</li> </ul> </li> <li>• Read data calibration. Adjustment of read DQS with read data byte.</li> <li>• Read DQS gating calibration for DDR3 only. Adjustment of DQS gate with read preamble window.</li> <li>• Write data calibration. Adjustment of write DQS with write data byte.</li> <li>• Write leveling calibration. Adjustment of write DQS with CK (DDR differential clock).</li> <li>• Read fine tuning. Adjustment of up to 7 delay-line units for each read data bit.</li> <li>• Write fine tuning. Adjustment of up to 3 delay-line units for each read data bit.</li> <li>• Periodic delay-line measurement for keeping its accuracy during refresh interval.</li> <li>• Additional fine tuning delay lines to adjust DDR clock delay, DDR clock duty cycle, DQS duty cycle.</li> </ul> </li> </ul>

*Table continues on the next page...*

Feature	Details
Power saving	<ul style="list-style-type: none"> <li>Support of dynamic voltage, frequency change and self-refresh mode entry through hardware and software negotiation with the system (request/acknowledge handshake) <ul style="list-style-type: none"> <li>Upon hardware or software self-refresh request assertion, further AXI requests are blocked (even before the assertion of the acknowledge).</li> <li>During self-refresh mode the system may deassert the operating clock of the MMDC for power saving.</li> <li>During self-refresh mode the clock (CK) that is driven to the DDR device will be gated for power saving.</li> </ul> </li> <li>Supports automatic self-refresh and power down entry and exit <ul style="list-style-type: none"> <li>In automatic self-refresh, the internal operating clock will be gated for power saving.</li> </ul> </li> <li>Supports fast and slow precharge power down in DDR3</li> <li>Automatic active and precharge power down timer per chip select (one chip select can enter power down while the other is still working)</li> <li>While CS (chip-select) is inactive (high) the command and address buses are not toggling for power saving.</li> <li>While DM (data masking) is high the associated DQ bus is not toggling (driven to "0") for power saving.</li> </ul>
DDR general	<ul style="list-style-type: none"> <li>Configurable timing parameters</li> <li>Configurable refresh scheme</li> <li>Page boundary crossing support <ul style="list-style-type: none"> <li>Automatically generates precharge command and activates the next row</li> </ul> </li> <li>Supports various ODT control schemes <ul style="list-style-type: none"> <li>Assertion or deassertion of ODT control per read or write accesses and for active or passive CS (chip-select)</li> </ul> </li> <li>Supports MRW and MRR commands for LPDDR2</li> <li>Software control in LPDDR2 mode for switching to derated timing parameters and/or update the refresh rate according to temperature sensor</li> <li>Debug and profiling capabilities</li> </ul>

## 32.2 External Signals

The table found here describes the external signals of MMDC.

**Table 32-2. MMDC External Signals**

Signal	Description	Pad	Mode	Direction
DRAM_ADDR[15:00]	Address Bus Signals	DRAM_A[15:0]	No Muxing	I/O
DRAM_CAS	Column Address Strobe Signal	DRAM_CAS	No Muxing	I/O
DRAM_CS[1:0]	Chip Selects	DRAM_CS[1:0]	No Muxing	I/O
DRAM_DATA[31:00]	Data Bus Signals	DRAM_D[31:0]	No Muxing	I/O
DRAM_DQM[7:0]	Data Mask Signals	DRAM_DQM[7:0]	No Muxing	I/O
DRAM_ODT[1:0]	On-Die Termination Signals	DRAM_SDODT[1:0]	No Muxing	I/O
DRAM_RAS	Row Address Strobe Signal	DRAM_RAS	No Muxing	I/O
DRAM_RESET	Reset Signal	DRAM_RESET	No Muxing	I/O
DRAM_SDBA[2:0]	Bank Select Signals	DRAM_SDBA[2:0]	No Muxing	I/O

*Table continues on the next page...*

**Table 32-2. MMDC External Signals (continued)**

Signal	Description	Pad	Mode	Direction
DRAM_SDCKE[1:0]	Clock Enable Signals	DRAM_SDCKE[1:0]	No Muxing	I/O
DRAM_SDCLK0_N	Negative Clock Signal 0	DRAM_SDCLK_0_B	No Muxing	I/O
DRAM_SDCLK0_P	Positive Clock Signal 0	DRAM_SDCLK_0	No Muxing	I/O
DRAM_SDWE	WE signal	DRAM_SDWE	No Muxing	I/O

## 32.3 Clocks

The table found here describes the clock sources for MMDC.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 32-3. MMDC Clocks**

Clock name	Clock Root	Description
aclk_fast_core_p0	mmdc_axi_clk_root	Fast clock (channel 1)
ipg_clk_p0	ipg_clk_root	Peripheral clock (channel 1)
aclk_fast_phy_p0	mmdc_axi_clk_root	Fast clock (channel 1 - PHY)

## 32.4 Functional Description

This section provides a complete functional description of the block.

### 32.4.1 Write/Read data flow

#### 32.4.1.1 Write data flow

- Write requests are received into an 8 entries request FIFO. Access is received only when there are at least two available entries. Each entry holds all of the AXI attributes.
  - If the burst length is greater than 8, the access splits into two accesses: one with burst length 8 and the other with the remainder.
  - The access can be performed as soon as the entire data phase of the associated write request is completed (all data beats were received).

2. A simple round-robin arbitration between the pending read and write accesses is performed, and the pointer to this stage's winner access is sent to the re-ordering buffer.
3. The reordering mechanism is activated to find the winner access, which is the access that best utilizes the DDR bus, based on its dynamic score. For further information see [Dynamic scoring mode \(Arbitration Winning Conditions\)](#).
4. The winner write access at the previous stage is received and is held for dispatch to the DDR logic.
5. When the DDR command control unit is ready to accept the write request, it issues (if needed) a precharge/active command to the DDR device according to the status of the bank model and the parameters of the timers.
6. The DDR logic drives the associated data to the DDR device through the DDR PHY.

### 32.4.1.2 Read data flow

1. Read requests are received into a 16 entry request FIFO in MMDC if there are at least two available entries. Each entry holds all of the AXI attributes.

#### NOTE

If the burst length is greater than 8, the access splits into 2 accesses (one with burst length 8 and the other with the remainder).

2. A simple round-robin arbitration between the pending read and write accesses is performed and the pointer to this phase's winner access is sent to the re-ordering buffer.
3. The reordering mechanism is activated to find the winner access, which is the access that best utilizes the DDR bus, based on its dynamic score. For further information see [Dynamic scoring mode \(Arbitration Winning Conditions\)](#).
4. The winner read access at the previous stage is sampled and is held for dispatch to the DDR logic. This read access will be dispatched when there is at least one free slot in the read data buffer to store the data.
5. When the DDR command control unit is ready to accept the read request, it issues (if needed) a precharge/active command to the DDR device according to the status of the bank model and the parameters of the timers.
6. The MMDC PHY samples the read data, and the DDR logic transfers the data to the associated slot in the read data buffer.
7. MMDC transfers the data back to the master.

## 32.4.2 MMDC initialization

Because the MMDC is disabled when the chip exits reset, no clock is driven to the DDR device and the whole interface towards the DDR device is inactive. The following steps are required to activate the MMDC properly.

### NOTE

To guarantee that the DRAM\_RESET and DRAM\_SDCKE signals are kept low during the power-up and reset sequences of the chip in DDR3 and LPDDR2 modes (as defined by JEDEC), you must connect those signals to pull-down resistors.

1. Set MDSCR[CON\_REQ], which sets the configuration request; note that because the MMDC is disabled, there is no need to poll the configuration acknowledge bit at MDSCR[CON\_ACK].
2. Configure the desired timing parameters at the MDCFG0, MDCFG1, MDCFG2, and MDOTC registers.
3. Configure the DDR type and other miscellaneous parameters at the MDMISC register.
4. Configure the required delay while leaving reset, at the MDOR register.
5. Configure the DDR physical parameters (density and burst length) at the MDCTL register.
6. Perform a ZQ calibration of the MMDC module to correctly initialize drive strengths.
7. Enable MMDC with the desired chip select at MDCTL[SDE\_0] (for chip select 0) and MDCTL[SDE\_1] (for chip select 1). At this point, MMDC starts the reset and initialization sequence related to DRAM\_RESET/DRAM\_SDCKE as defined by JEDEC.
8. Complete the initialization sequence as defined by JEDEC by issuing MRS/MRW commands for (ZQ, ODT, PRE, and so on). To issue those commands, configure the appropriate command and address at the MDSCR register.
9. Program the DDR mode registers by configuring the appropriate command and address at the MDSCR register.
10. Configure the power down and self-refresh entry and exit parameters at the MDPDC and MAPSR registers.
11. Configure the ZQ scheme at the MPZQHWCTRL and MPZQLP2CTRL registers.
12. Configure and activate the periodic refresh scheme at the MDREF register.
13. Deassert the configuration request by clearing MDSCR[CON\_REQ].

### NOTE

Steps 1 through 5 are non-blocking and can be done in any order.

Upon completion of these steps, MMDC is ready for work and to process AXI accesses.

**NOTE**

To achieve better timing and better precision, it is recommended that users configure the MMDC PHY delay parameters by operating either the automatic or manual calibration process. Before starting any calibration process, you must disable the periodic refresh scheme (MDREF[REF\_SEL] = 00) and then issue a manual refresh command by configuring MDSCR[CMD] to 2h. For further information, see [Calibration Process](#).

### 32.4.3 Configuring the MMDC registers

To safely modify MMDC's internal configuration registers, MMDC must be placed into configuration mode.

Use the following steps to enter configuration mode.

1. Issue a configuration request by setting MDSCR[CON\_REQ].
2. Poll on configuration acknowledge until it is set at MDSCR[CON\_ACK].

At this point, MMDC enters configuration mode and accessing the MMDC registers is permitted.

**NOTE**

During configuration mode, MMDC prevents further AXI accesses from being acknowledged.

Upon deassertion of MDSCR[CON\_REQ], MMDC leaves configuration mode and AXI accesses are processed.

### 32.4.4 MMDC Address Space

#### 32.4.4.1 Address decoding

MMDC supports up to two consecutive chip selects, each with the same density.

It is optional to configure the partition between the chip selects through MDASP[CS0\_END].

The incoming AXI address bus is 32 bits. MMDC decodes each access as follows:

1. chip select

2. bank number
3. row number
4. column number

The following registers in the MMDC define the DDR address space:

- MDMISC[DDR\_4\_BANK]—Defines either 4 or 8 banks in the DDR device
- MDCTL[DSIZ]—Defines the DDR data bus width of x16, x32 or x64
- MDMISC[BI]—Defines whether bank interleaving is on or off
- MDCTL[COL]—Defines the column size of the DDR device
- MDCTL[ROW]—Defines the row size of the DDR device

The following tables show address decoding examples for x16 and x32 bit DDR devices when bank interleaving is both on and off. It is assumed that the configuration is as follows: 8 banks (3 bits), 15 bit assignment for the row, and 10 bit assignment for the column. The total density is 256 MWords (512 Mbytes for x16 and 1 Gbyte for x32).

### NOTE

Chip selection is done by comparing the 7 most significant address bits (ARADDR[31:25]/AWADDR[31:25]) with MDASP[CS0\_END].

**NOTE**

In cases where this is an access to a non-initialized or disconnected chip select, behavior may be unexpected.

**32.4.4.2 Chip select settings**

MMDC drives the incoming access to either CS0 or CS1 by comparing the 7 most significant address bits (ARADDR[31:25]/AWADDR[31:25]) with MDASP[CS0\_END].

Generally, the total density per chip-select must be the same, and the total density per chip-select must be a power of two.

[Creating 4 Gbyte address space with 2 Gbyte CS density](#) and [Creating 2 Gbyte address spaces with 1 Gbyte CS density](#) show how to create a continuous address space and configure the MMDC accordingly.

**32.4.4.2.1 Creating 4 Gbyte address space with 2 Gbyte CS density**

If the DDR memory space allocation is 4 Gbytes, only one configuration of chip select partition is allowed.

The register MDASP[CS0\_END] should be set to 011\_1111 (partition at 2 Gbytes).

The figure below shows the associated memory space. In the case of DDR3 x64, this address space can be achieved by connecting four devices per chip select. Each device is x16 with density of 4 Gbytes.

**Figure 32-2. Chip select partition—2 Gbytes per chip select**

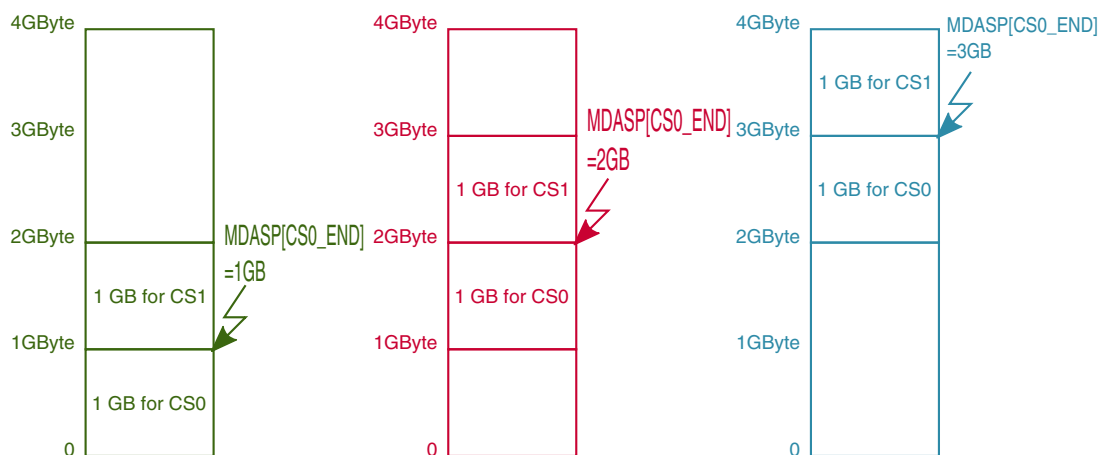

### 32.4.4.2.2 Creating 2 Gbyte address spaces with 1 Gbyte CS density

If the DDR memory space allocation is 2 Gbytes, there are three options for configuring the chip select partition: MDASP[CS0\_END] to 001\_1111 (1 Gbyte), MDASP[CS0\_END] to 011\_1111 (2 Gbytes), and MDASP[CS0\_END] to 101\_1111 (3 Gbytes).

If DDR memory space allocation is 2 Gbytes, there are three options for configuring the chip select partition:

- MDASP[CS0\_END] to 001\_1111 (1 Gbyte)
- MDASP[CS0\_END] to 011\_1111 (2 Gbytes)
- MDASP[CS0\_END] to 101\_1111 (3 Gbytes)

The figure below shows the associated memory space:

**Figure 32-3. Chip select partition—1 Gbyte per chip select**

### 32.4.4.3 Translation of AXI accesses to DDR accessesss

### 32.4.4.3.1 Example

Assume the AXI write access has the following attributes:

- Increment (awburst[1:0]=2'b01)
- AXI size of 64bits (awsize[2:0]=3'b011)
- AXI length of 2 (awlen[3:0]=4'b0001)
- AXI address with suffix 0x5 (non aligned)

Toward DDR3(MDMISC[DDR\_TYPE]=2'b00) with the following attributes:

- x32 (MDCTL[DSIZ]=2'b10)
- burst length of 8 (MDCTL[BL]=1'b1)

In this case the AXI alignment is every 8B (0x8) and the DDR boundary is every 4Bx8=32B(0x20).

The master expects to write the data to the following addresses: 0x5 (with WSTRB=0xE0), 0x8 (till 0xF).

The MMDC will issue one access toward the DDR as follows:

Write access toward logic address with suffix 0x0 (DDR boundary is 0x20 and 0x0 is the closest to 0x0) while address 0x0 till 0x4 are masked by DM (data masking signal) and address 0x10 till 0x1F are also masked by DM.

### 32.4.4.4 Address mirroring

When enabling this feature, address bits DRAM\_A3, DRAM\_A4, DRAM\_A5, DRAM\_A6, DRAM\_A7, DRAM\_A8, DRAM\_SDBA0, and DRAM\_SDBA1 behave differently according to the associated chip select.

This feature facilitates PCB board routing for devices on chip select 1, which are typically populated on the opposite side of the PCB from the devices on chip select 0.

#### NOTE

This feature is only supported for DDR3 memories. It is not supported for LPDDR2 memories.

The following table specifies the address mirroring options:

**Table 32-6. Address mirroring options**

MMDC pin	Chip select 0 pin	Chip select 1 pin
DRAM_A3	DRAM_A3	DRAM_A4

*Table continues on the next page...*

**Table 32-6. Address mirroring options (continued)**

MMDC pin	Chip select 0 pin	Chip select 1 pin

### 32.4.5 LPDDR2 and DDR3 pin mux mapping

The following table shows the pin mux mapping between LPDDR2 and DDR3. The i.MX DDR I/O pads corresponds with the DDR3 standard.

- In DDR3, all DRAM\_DATA, DRAM\_SDQS, and DRAM\_DQM data lines work with channel 0.
- In LPDDR2, DRAM\_DDQS[3:0], DRAM\_DATA[31:0] and DRAM\_DQM[3:0] work with channel 0. DRAM\_SDQS[7:4], DRAM\_DATA[63:32], and DRAM\_DQM[7:4] work with channel 1.

**Table 32-7. LPDDR2 and DRAM pin mux mapping**

## 32.4.6 Power Saving and Clock Frequency Change modes

### 32.4.6.1 Power saving general

MMDC supports multiple DDR power saving modes.

#### NOTE

At default, the power saving modes are disabled. These modes may dramatically decrease the power consumption of DDR memories.

- Self-refresh entry to the entire DDR device (for both chip select 0 and 1) can be activated through two mechanisms:
  - LPMD (Low Power Mode)
    - Hardware handshaking (LPMD/LPACK) with the clock module in the system
    - Software handshaking by setting the field MAPSR[LPMD] and polling MAPSR[LPACK]
    - Automatic entry by configuring the amount of idle cycle for triggering self-refresh entry through MAPSR[PST] and by clearing MAPSR[PSD]
  - DVFS (Dynamic Voltage and Frequency Change)

- Hardware handshaking (DVFS/DVACK) with the clock module in the system
- Software handshaking by setting the field MAPSR[DVFS] and polling MAPSR[DVACK]

### NOTE

If hardware or software requests for self-refresh entry were detected by the MMDC (even before the assertion of the LPACK), no write or read accesses will be acknowledged until the deassertion of those requests.

2. Automatic active/precharge power down entry to a specific chip select can be activated by configuring the ESDPDC register:
  - PWDT\_0/PWDT\_1 - define the number of idle cycles before entering power down, can be different value per chip select.
  - SLOW\_PD - In case of DDR3 memory is configured to use slow precharge power down then this bit should be set as well.
  - BOTH\_CS\_PS - The MMDC can either set each chip select independently to power down, according to its idle state, or set both chip selects to power down only if both in idle state for the configured period.
  - Few parameters must be configured in addition:
    - Timing parameters at ESDCFG0[tXP and tXPDLL].
    - ODT timing at ESDOTC[tAOFPD, tAONPD, tANPD and tAXPD]

### NOTE

It is possible to enter certain chip selects to low power consumption while the second chip select is activated.

3. Automatic precharge of all DDR banks to a specific chip select. Can be activated by configuring ESDPDC fields: PRCT\_0 and PRCT\_1. Each field determines a value loaded to a different chip select.

#### 32.4.6.2 Self refresh and Frequency change entry/exit

As described in [Power saving general](#), the MMDC supports two mechanisms that will cause the DDR device to enter self-refresh mode:

- LPMD (Low Power Mode) - For power saving purposes
- DVFS (Dynamic Voltage and Frequency Change) - For clock frequency changes

While the DDR device is in self-refresh mode, there is no need to provide periodic refresh commands.

The MMDC treats hardware/software handshaking of LPMD/DVFS in the same manner:

- Upon the assertion of LPMD/DVFS request, the following is done:
  - The MMDC blocks any further AXI accesses even before the acknowledge is asserted
  - Completes all opened AXI accesses
  - Closes (precharge) all banks in the appropriate timing
  - Drives self-refresh command by deasserting clock enable signal (DRAM\_SDCKE is driven to "0") together with a refresh command. This occurs after satisfying tRP/tRPA from the precharge all command.
  - Deasserts the clock (CK) that is driven to the DDR device
  - Asserts LPMD/DVFS acknowledge (LPACK/DVACK)
  - Allows deassertion of the operating clock of the MMDC (AXI clock)
- Upon the deassertion of LPMD/DVFS request, the following is done:
  - Operating clock of the MMDC must be turned on before LPMD/DVFS is deasserted
  - Starts driving the clock (CK) to the DDR device
  - After satisfying tCKSRX from clock renewal the clock enable signal (DRAM\_SDCKE) is asserted
  - LPMD/DVFS acknowledge (LPACK/DVACK) is deasserted
  - After satisfying tXS from the assertion of DRAM\_SDCKE, a refresh command is driven to the DDR device.
  - If ZQ calibration is enabled then tRFC is satisfied from the refresh command and a long ZQ command is driven.
  - tZQoper idle cycles are counted after the ZQ command.
  - After satisfying tDLLK from the assertion DRAM\_SDCKE, the MMDC returns to normal operation.

The figure below shows the timing diagram of the hardware/software handshaking of LPMD/DVFS:

**Figure 32-4. LPMD/DVFS Hardware/Software Handshaking**

Note for self-refresh:

- As soon as LPMD or DVFS requests are detected by either hardware or software handshaking, the MMDC will deassert the AXI ARREADY/AWREADY signals immediately to block further requests from the system.
- In case of automatic self-refresh, the internal operating clock will be negated to save power.

## 32.4.7 Reset

### 32.4.7.1 Hard reset

When hard reset is asserted (aresetn is driven to "0") while warm reset is deasserted (warm\_reset is driven to "0"), the entire MMDC will be initialized, including configuration/status registers and state machines.

In order to access the DDR device, the MMDC will then have to be reconfigured.

### 32.4.7.2 Warm reset

The MMDC supports warm reset signal. The warm reset signal must envelop the hard reset signal and then the MMDC will reset all the internal registers. The only registers that are not reset are those that are essential for returning it to normal operation without repeating the initialization sequence and without losing data stored in the memory (configuration/status registers won't be initialized).

For the successful operation of warm reset, the following steps must be performed:

- The MMDC must enter self-refresh mode. This can be achieved by either LPMD or DFVS requests
- Wait for LPMD or DVFS acknowledge
- Assert warm reset signal (i.e. drive warm\_reset to "1")
- Assert hard reset signal (i.e. drive aresetn to "0")
- Deassert hard reset signal
- Deassert warm reset
- Get out of the LPMD/DVFS mode

**Figure 32-5. Warm Reset Diagram**

### 32.4.7.3 Software reset

The MMDC supports software reset. When software reset is configured then the MMDC will reset all the internal registers except those that are essential for returning to normal operation without repeating the initialization sequence or without losing data stored in the memory (configuration/status registers won't be initialized).

The following steps should be performed for successful operation of software reset:

- The MMDC should enter self-refresh mode. This can be achieved by either LPMD or DFVS request.
- Wait for LPMD or DVFS acknowledge
- Assert software reset, by setting MDMISC[RST]
- Get out of the LPMD/DVFS mode

Normal operation can be resumed.

### 32.4.8 Refresh Scheme

The MMDC supports various automatic refresh options which can be configured via the MDREF register.

The periodic auto refresh can be triggered by the following clocks:

- 32KHz clock
- 64KHz clock
- MMDC operating clock

The refresh scheme of the MMDC is flexible and allows the system to configure the desired AXI accesses delay/latency in each refresh cycle.

The table below shows an example of four configurations of the refresh cycles that will be handled by the MMDC. Each configuration meets a refresh rate of 3.9us (tREFI, refresh command every 3.9us).

**Table 32-8. MMDC Refresh Scheme**

Option number	Description	REFR	REF_SEL	REF_CNT	DDR hang time
1	Issue 8 refresh commands every 31,250 ns	0x7 (8 refreshes)	0x2 (64KHz)	not needed	tRFC * 8
2	Issue 4 refresh commands every 15,625ns	0x3 (4 refreshes)	0x1(32KHz)	not needed	tRFC * 4
3	Issue 2 refresh commands every 7800ns	0x1(2 refreshes)	0x3 (fast counter)	7800/2.5 = 3120 (0xC30)	tRFC * 2
4	Issue 1 refresh command every 3900 ns	0x0 (1 refresh)	0x3 (fast counter)	3900/2.5 = 1560(0x618)	tRFC

### 32.4.9 Burst Length options towards DDR

The MMDC supports two kinds of burst lengths which can be configured through MDCTL[BL] as follows:

- In DDR3 mode, only burst length 8 can be used.
- In LPDDR2 mode, only burst length 4 can be used.

In DDR3 mode read/write accesses to the DDR are always 8 words (x16, x32, x64) and aligned in according to JEDEC standards.

In case of AXI INCREMENT, accesses that are not aligned the irrelevant data is masked in write accesses and ignored in read accesses. In case of AXI WRAP accesses, even if the access is not aligned, then the MMDC provides an internal optimization mechanism for better efficiency of the DDR data bus.

### 32.4.10 Exclusive accesses handling

The MMDC contains four exclusive monitors, each for dedicated ID as configured in MAEXIDR0 and MAEXIDR1.

- If legal read exclusive is received by the MMDC, the associated monitor is turned on.

- While the monitor is turned on upon legal write exclusive, the monitor will be turned off and the write will be completed successfully with EXOKAY.
- The following rules must be met for successful exclusive access:
  - Aligned access (the AXI address is aligned to the AXI size)
  - AXI single access (AXI burst length isn't greater than 1)
  - AXI size of up to 64 bits
  - AXI non-cachable access (i.e. ARCACHE[1]/AWCACHE[1] is equal "0" or ARCACHE[1]/AWCACHE[1] is equal "1" while ARCACHE[3:2]/AWCACHE[3:2] are equal "00")
  - AXI ID that matches one of the four exclusive IDs

Exclusive read behavior (first bullet also correct for non-exclusive accesses):

- In case of security violation, the read is blocked and is not sent to DDR. There are two options for response:
  - If ARCR\_SEC\_ERR\_EN (MAARCR[30]) is high, SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.
- If AXI exclusive rules violation occurs (as described above), the read access is not blocked and is sent to DDR. The data will be fetched and be driven to the master, but the type of response may be unpredicted.
- If none of the above occurs, the read is sent to the DDR. The exclusive monitor will be turned on and the response is ExOKAY
- If additional legal AXI read exclusive is received with the same ID before the AXI exclusive write, the monitor will be updated with the latest attributes.

Exclusive write behavior (first bullet also correct for non-exclusive accesses):

- In case of security violation, the write is blocked and is not sent to DDR, but the monitor will be kept on. There are two options for response:
  - If ARCR\_SEC\_ERR\_EN (MAARCR[30]) is high then SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.
- In case of AXI exclusive rules violation (as described above), the write is blocked and is not sent to DDR. In that case the type of response may be unpredicted.
- In case the exclusive write access has different AXI attributes, but the same ID as the read exclusive access, the write is blocked and is not sent to DDR and the monitor will be turned off. There are two options for response:
  - If ARCR\_EXC\_ERR\_EN (MAARCR[28]) is high then SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.
- In case of regular (non exclusive) write access is received to the same address or overlapping addresses then the write will be sent to the DDR and the monitor will be turned off.
- In case of legal write exclusive access is received with the same attributes as the read exclusive access while the monitor is on ( no write accesses occurred to the same

address between the read exclusive and write exclusive), then the write is sent to DDR and the response is EXOKAY. But, if the legal write exclusive is received while the monitor is off, the write is blocked and there are two options for response.

- If ARCR\_EXC\_ERR\_EN (MAARCR[28]) is high then SLV error is issued towards the Master, otherwise OKAY response is sent to the Master.

### 32.4.11 AXI Error Handling

The MMDC supports the AXI responses listed here.

- In case of AXI exclusive violation there are two options for response:
  - If MAARCR[28] is high then SLVError is issued towards the Master, Otherwise OKAY response is sent to the Master

#### NOTE

In case of read error MMDC drives zeros on the read data bus

## 32.5 Performance

### 32.5.1 Arbitration and reordering mechanism

#### 32.5.1.1 Arbitration General

The following specifies arbitration and reordering flow in MMDC towards the DDR.

- AXI read and write accesses are sampled in the associated queue.
- Read/write arbitration is handled to select the winning access.
- Winning access is sampled in the reordering queue
- Reordering mechanism is handled between valid requests that reside in the reordering queue to select the access that will be dispatched to the DDR.
  - The reordering is held in order to optimize the accesses and to maximize the utilization of the DDR bus
  - As soon as the reordered access is completed (indicated by end of response or data phase) then it is erased from the associated queue and the MMDC is ready to receive the next available access from the master

In general, the reordering/arbitration mechanism is based on dynamic priority mechanism, which compares dynamic priorities between valid entries in the reordering queue and issues the entry with highest dynamic priority towards the DDR Logic.

The selection of the winning access is based on two modes, which can be activated together, as following:

- Real time channel mode:
  - Accesses with QoS='f' (i.e. awqos[3:0]/arqos[3:0] = "f") will bypass all other requests towards the DDR
- Dynamic scoring mode:
  - The arbitration mechanism is based on dynamic priority. Relevant for the accesses with QoS smaller than 'f' or when real time channel mode is disabled.

### **NOTE**

Due to re-ordering and optimization mechanism (per different AXI ID), the transactions towards the DDR may be driven in a different ID order they were received by the AXI master. In similar way, the write response, read response or read data may be driven to the AXI master in a different ID order.

#### **32.5.1.2 Real time channel mode**

When real time mode is enabled (i.e MAARCR[ARCR\_RCH\_EN] = "1") , all requests with QoS='f' (i.e. awqos[3:0]/aqos[3:0] = "f") will bypass all other pending accesses towards the DDR. This mode is enabled by default.

#### **32.5.1.3 Dynamic scoring mode (Arbitration Winning Conditions)**

The arbitration between pending accesses in the MMDC is handled according to a dynamic priority of each access.

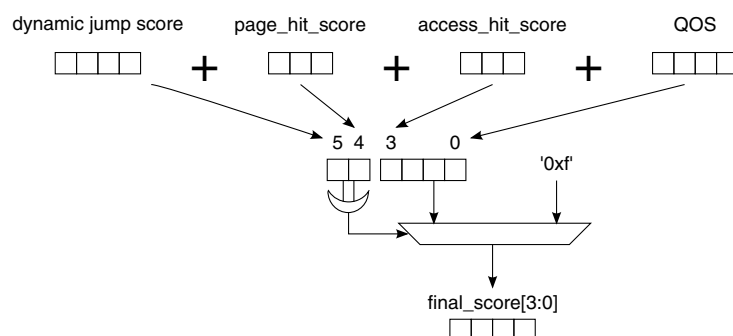

The dynamic priority (may be also called score) is calculated according to a sum of some factors (final\_score[3:0]), where part of them may be updated dynamically. The following will specify each scoring factor:

- MAARCR[ARCR\_PAG\_HIT] (Page hit score) - A static score which is taken into account in case the pending access has a page hit
- MAARCR[ARCR\_ACC\_HIT] (Access hit score) - A static score, which is taken into account in case the current access type (read/write) is the same as the access that has been dispatched to the DDR previously

- MAARCR[ARCR\_DYN\_JMP] (Dynamic jump score) - A dynamic score which is given to any pending access in case it was not chosen in the arbitration. The dynamic jump counter is limited by maximum value which is set in MAARCR[ARCR\_DYN\_MAX] .
- QoS score which is indicated through a sideband 4bits AXI signals (awqos[3:0]/ aqos[3:0]) and is driven by the AXI master per access

Note: In order to prevent an overflow in the total sum of scores, a clipping is held and selects the maximum score value of 'f' once a total scores sum is greater than 'f'.

The figure below shows the dynamic score calculations

**Figure 32-6. Dynamic score/priority calculation**

### 32.5.1.4 Guarding (aging) mechanism

The guarding mechanism (may be also called aging) is used to prevent a starvation of accesses.

As soon as the dynamic jump score reaches its maximum value (MAARCR[ARCR\_DYN\_MAX] ) then each time a pending request was not chosen in the arbitration, the "guarding" counter is incremented by 1. When the "guarding" counter reaches its predefined value, set in MAARCR[ARCR\_GUARD], the associated request gets the highest priority and will be chosen in the next arbitration cycle towards the DDR unless a real time channel (i.e access with QoS ="f") is arrived.

Note: In case real time channel has arrived then the dynamic score of the non real time channels won't increment in order to prevent a case where the "guarding" counter of more than one access has reached its limit.

## 32.5.2 Prediction mechanism

When prediction mechanism is enabled (i.e by configuring MDMISC[MIF3\_MODE]) then the MMDC predicts the chip-select, bank address and row address that is going to be issued towards the DDR before the access is physically dispatched towards DDR device.

That mechanism enables to prepare the DDR device with future accesses and improves the overall DDR performance.

This prediction mechanism operates in parallel to the reordering mechanism and may yield a prediction based on 3 levels of pending accesses:

1. Access in first stage of pipeline.
2. Valid access on AXI bus either read channel or write channel.
3. Valid access on special bus from arbitration - this access is chosen by the arbitration as the next miss access in its buffers

## 32.5.3 Special Optimization for accesses towards DDR3

In case an AXI read/write wrap non-aligned access is acknowledged in DDR3 mode with the same wrap boundary as the DDR wrap boundary then the MMDC will make an optimization and issue only one access towards the DDR, although all the accesses towards the DDR3 must be aligned.

For example: AXI write access with size of 128bits (awsize[2:0]=3'b100), length of 4 (awlen[3:0]=4'b0011) towards DDR3 x64 (burst length 8). In that case the AXI wrap boundary is 16Bx4=64B (0x40) and the DDR3 wrap boundary is 8Bx8=64B (0x40). If, for example, the AXI access is towards AXI address with suffix of 0x10 (non-aligned to 64B boundary) then the MMDC will get from the AXI master the data that is associated with addresses 0x10, 0x20, 0x30, 0x0. The MMDC will rearrange internally the data so it will match DDR3 alignment as following: 0x0, 0x10, 0x20, 0x30 and drive it in one access towards the DDR to address 0x0. The alternative was to issue two accesses towards the DDR with address 0x0 with different data masking

### NOTE

In read wrap access the same optimization is handled, while as soon as the critical AXI word is fetched from the DDR then it is driven immediately to the AXI master without buffering. Based on the example above, the master expects to fetch first the data that is associated with address 0x10. Therefore the MMDC will issue read access from address 0x0 of the DDR and as soon as the data that is associated with address 0x10 is received then it

will be driven back immediately to the master even before fetching the data of the further addresses.

## 32.6 MMDC Debug

### 32.6.1 Hardware debug monitor

The MMDC has a hardware debugging mechanism that monitors each access that is driven to the MMDC.

Every time this mechanism is enabled (setting of MADPCR0[DBG\_EN] to "1") then each access that will be dispatched to the DDR will be also observed in the I/O pads (i.e. over ipp\_do\_ddr\_debug[50:0]). The content of this bus is described in the table below.

**Table 32-9. Hardware monitor debugging**

Signal Name	Number of Bits	Description
acc_addr	[31:0]	AXI ADDRESS of the selected access
acc_type	1	access type of the selected access. "0" indicates write. "1" indicates read.
acc_id	[15:0]	AXI transaction ID of the selected access
valid_strobe	1	indication for a valid request . This signal will be asserted for 1 clock cycle

The fields above are organized as following:

MMDC\_DEBUG[50:0] = { 1'b0,valid\_strobe,acc\_id,access\_type,addr }

These signals are sent to IOMUX, in IOMUX user can configure it to be output from the chip for debug usage.

### 32.6.2 Step By Step (SBS) software monitor

The MMDC has a Step By Step (SBS) software debugging mechanism that monitors each access that is driven to the MMDC.

Every time this mechanism is triggered then one AXI access will be dispatched to the DDR and in parallel its attributes will be observed in a status register.

Once the "step by step" is enabled (i.e. MADPCR0[SBS\_EN] is "1") then all accesses to the DDR device will be halted.

Setting MADPCR0[SBS] to "1" will dispatch the access that is pending in the head of the MMDC queue (read or write). Upon every setting of MADPCR0[SBS]:

- The AXI attributes of the access will be sampled in the associated MASBS0 and MASBS1 fields
- MADPCR0[SBS] will be cleared automatically.

Setting again MADPCR0[SBS] to "1" will dispatch the next pending access in the MMDC queue.

## 32.7 MMDC Profiling

The profiling mechanism provides the ability to calculate the DDR utilization together with read and write accesses statistics towards DDR per given period of time.

MMDC supports the following profiling counters:

- MADPSR0 (Total cycles count) - Indicates the total amount of cycles of the profiling period (up to  $2^{32}$  cycles)
- MADPSR1 (Busy cycles count) - Indicates the total busy cycles during the profiling period
- MADPSR2 (Total read accesses count) - Indicates the total read accesses towards MMDC during the profiling period
- MADPSR3 (Total write accesses count) - Indicates the total write accesses towards MMDC during the profiling period
- MADPSR4 (Total read bytes count) - Indicates total bytes that were read from MMDC during the profiling period
- MADPSR5 (Total write bytes count) - Indicates total bytes that were written to MMDC during the profiling period

All profiling items described above are disabled by default. The following describes how to control the profiling mechanism:

- MADPCR0[DBG\_EN] enables profiling.
- MADPCR0[PRF\_FRZ] stops/freezes the profiling for example in case user wishes to perform DDR profiling per specific task. In order to resume profiling then MADPCR0[PRF\_FRZ] should be cleared.
- MADPCR0[DBG\_RST] clears all profiling counters
- MADPCR0[CYC\_OVF] indicates whether an overflow occurred in the total cycles counter (i.e. total amount of cycles are greater than  $2^{32}$ ). This field can only be cleared by writing '0'.

Read/Write statistics can be collected per specific AXI ID (16bits). The following fields in MADPCR1 register determines which AXI-ID or AXI-ID's to monitor:

- PRF\_AXI\_ID defines which AXI IDs are taken for profiling. Default value is 16'h0.
- PRF\_AXI\_ID\_MASK defines which bits from PRF\_AXI\_ID will be compared with AXI ID of read/write access. "1" means to monitor the associated bit and "0" means don't care. Default value is 16'h0000, meaning all IDs are monitored

So the AXI-IDs to be monitored are calculated according to the following equation:

$$(AXI-ID \& PRF\_AXI\_ID\_MASK) \text{ Xnor } (PRF\_AXI\_ID \& PRF\_AXI\_ID\_MASK)$$

For example if AXI ID's between A100 till A1FF are wished to be monitored then the following should be configured:

- PRF\_AXI\_ID = A100
- PRF\_AXI\_ID\_MASK = FF00

## 32.8 LPDDR2 Refresh Rate Update and Timing Derating

LPDDR2 devices may have a temperature sensor that is used to determine an appropriate refresh rate and whether AC timing derating is required. The status of the temperature sensor can be read through MRR command from LPDDR2 MR4 register.

The MMDC supports refresh update and timing derating mechanism on the fly. The following specify how to use that mechanism:

- Perform periodic polling on MR4 LPDDR2 register using MRR command
- Read MDMRR register and analyze the MR4 indication
- In case refresh rate update and/or AC timing derating is required then it is needed to update MDREF and/or MDMR4[tRCD\_DE, tRC\_DE, tRAS\_DE, tRP\_DE, tRRD\_DE] parameters

### NOTE

MDMR4[tRCD\_DE, tRC\_DE, tRAS\_DE, tRP\_DE, tRRD\_DE]  
are referred to the associated values configured at  
MDCFG3LP[tRC\_LP, tRP\_LP, tRCD\_LP], MDCFG1[tRAS],  
MDCFG2[tRRD]

- Assert MDMR4[UPDATE\_DE\_REQ]
- When the MMDC switch to the new values then an acknowledge will be indicated at MDMR4[UPDATE\_DE\_ACK]

## 32.9 DLL Off mode

DLL Off mode is supported only in DDR3 and let operating the DDR in low frequency (i.e. below 125MHz as defined in JEDEC standard).

For further details refer to DLL-off Mode chapter in the standard.

The following steps should be executed in order to switch from DLL on to DLL off mode:

- Assert CON\_REQ signal and wait to CON\_ACK assertion.
- Disable power down timers that can conflict with this sequence, such as: MAPSR[PSD], MDPDC[PWDT\_1], MDPDC[PWDT\_0], MDPDC[PRCT\_0], MDPDC[PRCT\_1].
- Execute precharge all banks command (via MDSCR).
- Execute MRW command to MR1 and disable RTT Nom (A9,A6,A2 =0) and DLL ON (A0 =1).
- Execute MRW command to MR2 in order to update CWL to 6.
- Execute MRW command to MR0 in order to update CL to 6.
- De-assert CON\_REQ signal.
- Enter self refresh mode. For further information refer to [Self refresh and Frequency change entry/exit](#).
- At self refresh entry acknowledge , Change to the desired frequency.
- Exit self refresh mode.
- Assert CON\_REQ and wait to CON\_ACK assertion.
- Enable Pull Down resistors on DQS (through the I/O-MUX ).
- Configure the MMDR register as following:
- Update tCWL =6 and tCL =6 to meet the values configured in the DDR device. (MDCFG0, MDCFG1)
- Disable ODT resistor (i.e. set MPODTCTRL to "0").
- Disable DQS gating (i.e. set MPDGCTRL0[DG\_DIS] to "1").
- Enable required power down timers that were disabled, such as: MAPSR[PSD], MDPDC[PWDT\_1], MDPDC[PWDT\_0], MDPDC[PRCT\_0], MDPDC[PRCT\_1].
- De-assert CON\_REQ and wait for de-assertion of CON\_ACK.

The following steps should be executed in order to switch from DLL off to DLL on:

- Execute precharge all banks command (via MDSCR).
- Enter self refresh mode. For further information refer to [Self refresh and Frequency change entry/exit](#).
- At self refresh entry acknowledge , Change to the desired frequency.
- Exit self refresh mode

- Assert CON\_REQ and wait to CON\_ACK assertion.
- Disable power down timers that can conflict with this sequence, such as: MAPSR[PSD], MDPDC[PWDT\_1], MDPDC[PWDT\_0], MDPDC[PRCT\_0], MDPDC[PRCT\_1].
- Execute MRW command to MR1 and enable RTT Nom (A9,A6,A2 ) and DLL ON (A0 =0 ).
- Execute MRW command to MR0 to reset the DLL (A8) and update CL value
- Execute MRW command to MR2 in order to update CWL value.
- Execute ZQ commnad.
- Reconfigure MMDC BLOCK
- Update tCWL and tCL to meet the values configured to the memory. (MDCGFG0, MDCFG1)
- Enable ODT resistor (i.e. MPODTCTRL register)
- Enable DQS gating (i.e. set MPDGCTRL0[DG\_DIS] to "0").
- Disable Pull Down resistors on DQS (through the I/O-MUX ).
- Enable required power down timers that were disabled, such as: MAPSR[PSD], MDPDC[PWDT\_1], MDPDC[PWDT\_0], MDPDC[PRCT\_0], MDPDC[PRCT\_1].
- De-assert CON\_REQ and wait for de-assertion of CON\_ACK.

## 32.10 ODT Configuration

The MMDC supports two DRAM\_ODT signals (DRAM\_ODT for each DRAM\_CS) in DDR3 mode in order to allow the DDR device to turn on/off its termination resistors. The MMDC suggests various configuration for the assertion of the ODT signals as well as configuration of several related timing.

The following specifies the options for configuring the assertion of DRAM\_ODT signals:

- Assert DRAM\_ODT signal for the non active DRAM\_CS in write. For example : when this bit asserted - if writing to DRAM\_CS0 the DRAM\_ODT of DRAM\_CS1 will be asserted. This is done by setting MPODTCTRL[0] to "1"
- Assert DRAM\_ODT signal for the active DRAM\_CS in write by by setting MPODTCTRL[1] to "1"
- Assert DRAM\_ODT signal for the non active DRAM\_CS in read by by setting MPODTCTRL[2] to "1"
- Assert DRAM\_ODT signal for the active DRAM\_CS in read by by setting MPODTCTRL[3] to "1"

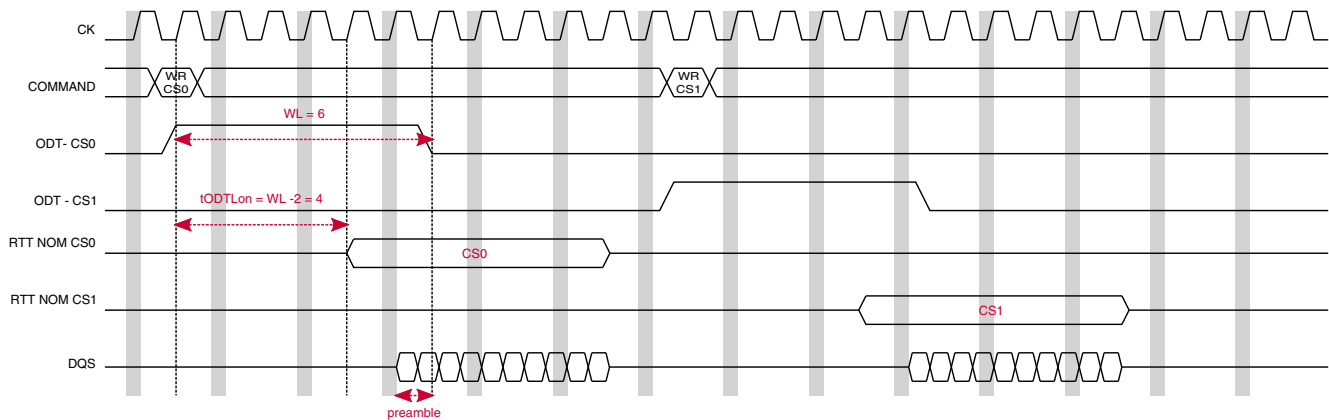

MDOTC register controls the timing for the DRAM\_ODT signals assertion.

**NOTE**

tODTLon determines the delay between DRAM\_ODT signal and the associated RTT, where according to JEDEC standard it equals WL(write latency) - 2. Therefore, the value configured to MDOTC[tODTLon] field should correspond with the value configured to MDCGFG1[tCWL].

In precharge power down mode, when all banks are closed, the assertion of ODT corresponds with tAOFPD and tAONPD which are configured in MDOTC register.

The figure below shows timing diagram of DRAM\_ODT and RTT signals while MPODTCTRL[0] is set to "1" (i.e. assertion of DRAM\_ODT to the non active DRAM\_CS in write access command) and MDOTC[tODTLon] is set to 4.

**Figure 32-7. ODT - Timing Diagram DDR3 WL=6, BL=8**

## 32.11 Calibration Process

The MMDC offers various calibration processes that are used to obtain better timing accuracy, board skew compensation and I/O pad driving strength adjustment.

Each calibration process can be performed either automatically (hardware) or manually (software), though the manual method is typically reserved for debugging purposes. The following calibration processes are supported:

**NOTE**

Power saving features should be disabled before the calibration process begin. (Such as: MDPDC[PWDT#], MDPDC[PRCT#], MAPSR[PSD])

- ZQ calibration for external DDR device (in DDR3 through ZQ calibration command and in LPDDR2 through MRW command)
  - Can be handled automatically for ZQ Short (periodically) and ZQ Long (at exit from self-refresh)
  - Can be handled manually at ZQ INIT
- ZQ calibration for i.MX DDR I/O pads for calibrating the DDR driving strength
  - The sequence can be handled automatically by hardware
  - The sequence can be handled step by step manually by software
- Read DQS gating calibration for DDR3 only. Adjustment of DQS gate with read preamble window. For further information refer to [Read DQS Gating Calibration](#)
- Read data calibration. Adjustment of read DQS with read data byte. For further information refer to [Read Calibration](#)
- Write data calibration. Adjustment of write DQS with write data byte. For further information refer to [Write Calibration](#)
- Write leveling calibration. Adjustment of write DQS with CK (DDR differential clock). For further information refer to [Write leveling Calibration](#)
- Read fine tuning. Adjustment of up to 7 delay-line units for each read data bit.
- Write fine tuning. Adjustment of up to 3 delay-line units for each read data bit.

### NOTE

Before starting any calibration process that involves the DDR3 device MPR mode or write leveling calibration, the following should be done:

- Disable the periodic refresh scheme (i.e. setting MDREF[REF\_SEL] = "00") and then issue manual refresh command burst by configuring MDSCR[CMD]= 0x2. At the end of the calibration it is needed to enable the periodic refresh scheme.
- Disable the automatic power saving mode (i.e set MAPSR[PSD] = "1").

## 32.11.1 delay-line

Each of the calibration processes controls several delay-lines for aligning data and strobes.

By default the delay-line is configured to generate 1/4 clock cycle of delay. The maximum delay that may be issued by the delay-line, while configured to the value 127, is as following:

- In BCS, -40C, 1.21V - 1.6ns.
- In WCS, 125C, 0.99V - 3.8ns

Moreover, when the operating clock is at the maximum allowed frequency, as appeared in the features list, then the delay-line is capable to issue a configurable delay of up to 1/2 clock cycle.

### **NOTE**

At the beginning of the calibration process the initial value of the delay-line must be a valid value (i.e. the strobes must be somewhere among the associated data window) though it might not be the optimal value. The delay-line calibration should be done after Read DQS gating and write-leveling calibrations.

In order to generate an adequate delay during normal operation of the MMDC the delay-line is going through an automatic measurement process during the refresh period of the DDR device

## **32.11.2 ZQ calibration**

The MMDC supports ZQ calibration process to calibrate the driving strength of the i.MX DDR I/O pads as well as driving ZQ commands to calibrate the external DDR device driving strength.

The first i.MX ZQ calibration (after booting the processor) is performed prior to turning on the MMDC. Subsequent i.MX ZQ calibrations may be executed in parallel to the DDR ZQ calibration. The MMDC supports 2 types of ZQ calibration commands: short and long.

The ZQ long calibration is executed during power up sequence, when existing self-refresh mode or when exiting slow precharge power down (DLL lock can be done in parallel). The ZQ short calibration is executed periodically according to a configurable timer defined by MPZQHWCTRL[ZQ\_HW\_PER].

The field MPZQHWCTRL[ZQ\_MODE] determines whether the MMDC will execute ZQ calibration to i.MX DDR I/O pads and/or issue ZQ short/long command to the DDR device.

The MMDC supports both automatic (hardware) and manual (software) ZQ calibration process for the i.MX DDR I/O pads.

It is possible to perform automatic (hardware) ZQ calibration only once (i.e. non-periodical) by asserting MPZQHWCTRL[ZQ\_HW\_FOR].

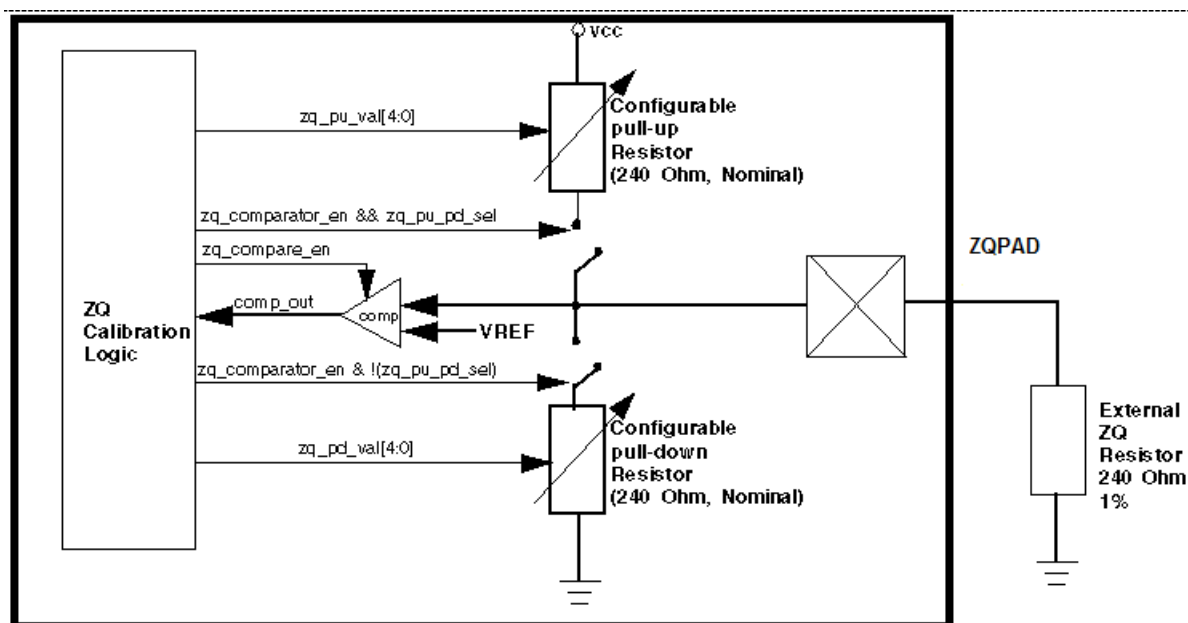

Figure 32-8. MMDC ZQ IF with PAD

### 32.11.2.1 ZQ automatic (hardware) calibration process

The ZQ automatic calibration lasts 11 steps. 5 steps for the pull up resistors calibration and 6 for the pull down resistors calibration.

The calibration control interface with ZQ pin is described below:

The calibration process is as follows:

#### 32.11.2.1.1 ZQ automatic Pull-up calibration

The MMDC perform a handshaking mechanism with the i.MX ZQ calibration pad automatically

as following:

1. The MMDC drives `zq_comparator_en` to "1"
2. The MMDC waits few cycles according to `MPZQHWCTRL[EARLY_COMPARATOR_EN_TIMER]`
3. The MMDC drives `zq_pu_pd_sel` to "1" for indication of pull-up calibration and drives `zq_pu_val[4:0] = 5'b00000`
4. MMDC drives `zq_pu_val[4]` to "1"
5. MMDC asserts `zq_compare_en`
6. MMDC waits few cycles according to `MPZQSWCTRL[ZQ_CMP_OUT_SMP]` before sampling the comparator output (i.e `zq_comp_out`). If `zq_comp_out` is "1"

then it means that the output voltage is greater than  $V_{dd}/2$  (i.e. internal resistor is less than 240 ohm) and drives bit `zq_pu_val[4]` to "1" else it drives `zq_pu_val[4]` to "0"

7. MMDC deasserts `zq_compare_en`
8. MMDC repeats steps 4- 7 for `zq_pu_val` bits 3 to 0
9. MMDC drives ZQ calibration result to `MPZQHWCTRL[ZQ_HW_PU_RES]`
10. MMDC advances to pull-down calibration

### 32.11.2.1.2 ZQ automatic Pull-down calibration

1. The MMDC drives `zq_pu_pd_sel` to "0" for indication of pull-down calibration and drives `zq_pd_val[4:0] = 5'b00000`
2. MMDC drives `zq_pd_val[4]` to "1"
3. MMDC asserts `zq_compare_en`
4. MMDC waits few cycles according to `MPZQSWCTRL[ZQ_CMP_OUT_SMP]` before sampling the comparator output (i.e `zq_comp_out`). If `zq_comp_out` is "1" then it means that the output voltage is greater than  $V_{dd}/2$  (i.e. internal resistor is less than 240 ohm) and drives bit `zq_pd_val[4]` to "0" else it drives `zq_pd_val[4]` to "1"
5. MMDC deasserts `zq_compare_en`
6. MMDC repeats steps 12- 15 for `zq_pd_val` bits 3 to 0
7. MMDC drives ZQ calibration result to `MPZQHWCTRL[ZQ_HW_PD_RES]`
8. MMDC deassert `zq_comparator_en` to indicate the completion of the ZQ calibration

### 32.11.2.2 ZQ software calibration process

The ZQ calibration can be done also in software. However since software ZQ calibration is much slower than hardware calibration it should be used mainly for debugging.

Software should configure the ZQ calibration parameters (Pull-up or Pull-down and their value) then assert the `MPZQSWCTRL[ZQ_SW_FOR]` bit. Then software should wait till `ZQ_SW_FOR` is de-asserted and use `ZQ_SW_RES` status bit in order to calculate the next ZQ calibration parameters.

### 32.11.2.3 ZQ calibration commands

Before the MMDC can issue a `ZQCL/ZQCS` command to the memory it should precharge all memory banks and wait `tRP` period. A single ZQ command can be issued to all devices as long as the devices don't share the same ZQ resistor.

When the MMDC issues the ZQ command it should also drive `A10` (long or short command) and `CS` (0, 1 or both).

The MMDC must keep the memory lines quiet (except for CK) for the ZQ calibration time as defined in the Jedec (512 cycles for ZQCL after reset, 256 for other ZQCL and 64 for ZQCS).

### 32.11.3 Read DQS Gating Calibration

The read DQS gating calibration is used to adjust the read DQS gating with the middle of the read DQS preamble.

The DQS gating includes a delay of up to 7 cycles (The delay is chosen according to two fields MPDGCTRL#[DG\_HC\_DEL#] and MPDGCTRL#[DG\_DL\_ABS\_OFFSET#]

Each DQS has its own delay-line. The DQS gating process can be done for all DQS in parallel.

#### NOTE

In LPDDR2 mode hardware Read DQS gating should be disabled and Pull-up/pull-down resistors on DQS/DQS# should be enabled while ODT resistors must be disconnected.

In DDR3\_x64 mode activation of the calibration is done by setting MPDGCTRL0[HW\_DG\_EN] at address 0xBASE0\_083C

#### 32.11.3.1 Hardware DQS Gating Calibration

- There are two modes of operations:
  - Calibration with the MPR (Multi Purpose Register)
  - Calibration with MMDC pre-defined values

##### 32.11.3.1.1 Hardware DQS Calibration with MPR

The following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required by the standard.
2. Enter the DDR device into MPR mode through MRS commands
3. Configure the MMDC to work with MPR mode by asserting MPPDCMPR2[MPR\_CMP]
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD\_DL\_ABS\_OFFSET#]) will place the read DQS somewhere inside the read DQ window

5. Start the calibration process by asserting MPDGCTRL0[HW\_DG\_EN]

### 32.11.3.1.2 Hardware DQS Calibration with pre-defined value

In case pre-defined mode is used, (i.e. MPPDCMPR2[MPR\_CMP]) is cleared, then the following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required by the standard.
2. Configure the pre-defined value, which reflects the value that will be written and compared through the read calibration, to MPPDCMPR1[PDV1, PDV2]
3. Issue write access to the external DDR device by setting MPSWDAR0[SW\_DUMMY\_WR] = 1 (MMDC will generate internally write access without intervention of the system towards bank 0, row 0, column 0)
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD\_DL\_ABS\_OFFSET#] ) will place the read DQS somewhere inside the read DQ window
5. Start the calibration process by asserting MPDGCTRL0[HW\_DG\_EN]

The following steps will be executed automatically by the MMDC for both modes (MPR and Pre-defined value):

6. MMDC waits till the read DQS delay-line is updated with the absolute delay value for all bytes at MPDGCTRL#[DG\_HC\_DEL#] and MPDGCTRL#[DG\_DL\_ABS\_OFFSET#] and also satisfying the Tmod + 4 requirement
7. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPDGCTRL0[DG\_CMP\_CYC] assuming that the data has arrived from the DDR device.
8. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point. If the comparison passes then MMDC advances to step 14
9. MMDC resets the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST\_RD\_FIFO] = 1
10. MMDC increments the read DQS gating delay of each byte by half cycle (i.e. MPDGCTRL#[DG\_HC\_DEL#] + 1)
11. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPDGCTRL0[DG\_CMP\_CYC] assuming that the data has arrived from the DDR device.
12. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8).

13. If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point and it is needed to repeat steps 9-12. If the comparison passes then MMDC stores the value of the temporary low boundary and advances to next step
14. MMDC increments the read DQS gating delay-line of each byte by half cycle (i.e.  $\text{MPDGCTRL}\#[\text{DG\_HC\_DEL}\#] + 1$ ) and issue measurement process of the read DQS gating delay-line to update itself with the new value
15. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to  $\text{MPDGCTRL0}[\text{DG\_CMP\_CYC}]$  assuming that the data has arrived from the DDR device.
16. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8)
17. If the comparison passes then it indicates that the read DQS gating is asserted inside the read preamble window and it is needed to repeat steps 14-16. If the comparison fails then MMDC stores the value of the temporary upper boundary and starts searching the adequate low and high boundaries
18. MMDC returns to the temporary low boundary minus half cycle and issue measurement process of the read DQS gating delay-line to update itself with the new value
19. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to  $\text{MPDGCTRL0}[\text{DG\_CMP\_CYC}]$  assuming that the data has arrived from the DDR device.
20. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8)
21. If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point and it is needed to repeat steps 22-23. If the comparison passes then MMDC stores the value of the adequate low boundary and advances to step 24
22. MMDC resets the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting  $\text{MPDGCTRL}[\text{RST\_RD\_FIFO}] = 1$
23. MMDC increments the read DQS gating delay of each byte by 1 (i.e.  $\text{MPDGCTRL}\#[\text{DG\_DL\_ABS\_OFFSET}\#] + 1$ ) and issue measurement process of the read DQS gating delay-line to update itself with the new value and advances to step 19
24. MMDC returns to the temporary upper boundary minus half cycle and issue measurement process of the read DQS gating delay-line to update itself with the new value
25. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to  $\text{MPDGCTRL0}[\text{DG\_CMP\_CYC}]$  assuming that the data has arrived from the DDR device.
26. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8)

27. If the comparison passes then it indicates that the read DQS gating is asserted inside the read preamble window and it is needed to repeat steps 28-29. If the comparison fails then MMDC stores the value minus 1 of the adequate upper boundary and advances to step 30
28. MMDC resets the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting `MPDGCTRL[RST_RD_FIFO] = 1`
29. MMDC increments the read DQS gating delay of each byte by 1 (i.e. `MPDGCTRL#[DG_DL_ABS_OFFSET#] + 1`) and issue measurement process of the read DQS gating delay-line to update itself with the new value and advances to step 25
30. After the MMDC finds the window boundary (lower and upper) of each read data byte then it stores the average between lower and upper boundaries at the associated `MPDGCTRL#[DG_DL_ABS_OFFSET#]` and issue measurement process of the read DQS delay-line to update itself with the new value.
31. MMDC indicates that the read DQS gating calibration had finished by setting `MPDGCTRL0[HW_DG_EN] = 0`
32. Exit the DDR device from MPR mode through MRS command
33. Read the upper boundary that was found: `MPDGHWST#[HW_DG_UP#]`. This field is 11 bits, 7 LSB bits correspond to `MPDGCTRL#[DG_DL_ABS_OFFSET#]` upper limit value and 4 MSB bits correspond to `MPDGCTRL#[DG_HC_DEL#]` upper limit value.
34. Set `MPDGHWST#[HW_DG_UP#[6:0]]` to `MPDGCTRL#[DG_DL_ABS_OFFSET#]`.
35. Set `(MPDGHWST#[HW_DG_UP#[10:7]] - 1)` to `MPDGCTRL#[DG_HC_DEL#]`. (We set the DQS gating value to be the upper limit value minus 1 half cycle)

### 32.11.3.2 SW read DQS gating Calibration

- There are two modes of operations:
- Calibration with the MPR (Multi Purpose Register)
- Calibration with MMDC pre-defined values

#### 32.11.3.2.1 SW read Calibration with MPR

The following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required by the standard.
2. Enter the DDR device into MPR mode through MRS commands
3. Configure the MMDC to work with MPR mode by asserting `MPPDCMPR2[MPR_CMP]`

4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. `MPRDDLCTL[RD_DL_ABS_OFFSET#]` ) will place the read DQS somewhere inside the read DQ window

### 32.11.3.2.2 SW read Calibration with pre-defined value

In case pre-defined mode is used, (i.e. `MPPDCMPR2[MPR_CMP]`) is cleared, then the following steps should be executed:

1. Precharge all active banks (Can be done through `MDSCR`) as required by the standard.
2. Configure the pre-defined value, which reflects the value that will be written and compared through the read calibration, to `MPPDCMPR1[PDV1, PDV2]`
3. Issue write access (with any legal DDR address) to external DDR device
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. `MPRDDLCTL[RD_DL_ABS_OFFSET#]` ) will place the read DQS somewhere inside the read DQ window

The following steps should be executed automatically by the MMDC for both modes (MPR and Pre-defined value):

5. Configure the read DQS delay-line to issue zero delay by setting `MPDGCTRL#[DG_DL_ABS_OFFSET#] = 0` and `MPDGCTRL#[DG_HC_DEL#] = 0`
6. Force the delay line to measure itself and to issue the requested read delay by configuring `MPMUR[FRC_MSR] = 1`
7. Wait 16 DDR cycles till the read DQS delay-line is updated with the absolute delay value for all bytes
8. Issue read command (with the legal DDR address chosen in step 3) from the external DDR device
9. Waits 16 or 32 cycles (according to `MPDGCTRL0[DG_CMP_CYC]`) assuming that the data has arrived from the DDR device.
10. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point. If the comparison passes then advance to step 15
11. MMDC resets the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting `MPDGCTRL[RST_RD_FIFO] = 1`
12. Increment the read DQS gating delay of each byte by half cycle (i.e. `MPDGCTRL#[DG_HC_DEL#] + 1`)
13. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to `MPDGCTRL0[DG_CMP_CYC]`) assuming that the data has arrived from the DDR device.

14. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point and it is needed to repeat steps 11 - 14. If the comparison passes then advance to step 15
15. Store the temporary lower boundary and start searching the temporary upper boundary
16. MMDC resets the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting `MPDGCTRL[RST_RD_FIFO] = 1`
17. Increment the read DQS gating delay of each byte by half cycle (i.e. `MPDGCTRL#[DG_HC_DEL#] + 1`)
18. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to `MPDGCTRL0[DG_CMP_CYC]` assuming that the data has arrived from the DDR device.
19. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8).
20. If the comparison passes then it indicates that the read DQS gating is asserted inside the read preamble window and it is needed to repeat steps 16-19. If the comparison fails then it is needed to store the value of the temporary upper boundary and starts searching the adequate low and high boundaries
21. Load the temporary low boundary minus half cycle into the associated `MPDGCTRL#[DG_HC_DEL#]`
22. Reset the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting `MPDGCTRL[RST_RD_FIFO] = 1`
23. Increment the read DQS gating delay of each byte by 1 (i.e. `MPDGCTRL#[DG_DL_ABS_OFFSET#] + 1`) and force the delay line to measure itself and to issue the requested read DQS delay by configuring `MPMUR[FRC_MSR] = 1`
24. Issue read command to the external DDR devices and waits 16 or 32 cycles (according to `MPDGCTRL0[DG_CMP_CYC]`) assuming that the data has arrived from the DDR device.
25. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8)
26. If the comparison fails then it indicates that the read DQS gating is asserted in illegal time point and it is needed to repeat steps 22-26. If the comparisons passes then advance to the next step.
27. Store the adequate lower boundary
28. Load the temporary upper boundary minus half cycle into the associated `MPDGCTRL#[DG_HC_DEL#]`
29. Reset the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting `MPDGCTRL[RST_RD_FIFO] = 1`

30. Increment the read DQS gating delay of each byte by 1 (i.e.  $\text{MPDGCTRL}\#[\text{DG\_DL\_ABS\_OFFSET}\#] + 1$ ) and force the delay line to measure itself and to issue the requested read DQS delay by configuring  $\text{MPMUR}[\text{FRC\_MSR}] = 1$
31. Issue read command to the external DDR devices and waits 16 or 32 cycles (according to  $\text{MPDGCTRL0}[\text{DG\_CMP\_CYC}]$  assuming that the data has arrived from the DDR device.
32. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8)
33. If the comparison passes then it is needed to repeat steps 29-32. If the comparisons fails then advance to the next step.
34. Reset the read FIFO (to the inverted pre-defined/MPR value) and it's pointers by setting  $\text{MPDGCTRL}[\text{RST\_RD\_FIFO}] = 1$
35. Store the adequate upper boundary.
36. Keep the  $\text{MPDGCTRL}\#[\text{DG\_DL\_ABS\_OFFSET}\#]$  value of the upper limit.
37. Set  $\text{MPDGCTRL}\#[\text{DG\_HC\_DEL}\#] = (\text{MPDGCTRL}\#[\text{DG\_HC\_DEL}\#] - 1)$ . (We set the DQS gating value to be the upper limit value minus 1 half cycle)
38. Issue the requested read DQS delay by configuring  $\text{MPMUR}[\text{FRC\_MSR}] = 1$
39. Exit the DDR device from MPR mode through MRS command

### 32.11.4 Read Calibration

The read calibration is used to adjust the read DQS with read data byte.

It is assumed that the read DQS gating calibration process is completed prior to the read calibration.

#### NOTE

In DDR3 mode, the activation of the calibration is done by setting  $\text{MPRDDLHWCTL}[\text{HW\_RD\_DL\_EN}]$  at address  $0x\text{BASE0\_0860}$  In LP2\_x16, LP2\_x32 the activation of the calibration is done by setting  $\text{MPRDDLHWCTL}[\text{HW\_RD\_DL\_EN}]$  at address  $0x\text{BASE0\_0860}$ .

#### 32.11.4.1 Hardware (automatic) Read Calibration

- There are two modes of operations:
- Calibration with the MPR (Multi Purpose Register)/DQ calibration(LPDDR2)
- Calibration with MMDC pre-defined values

### 32.11.4.1.1 Hardware (automatic) Calibration with MPR (DDR3) /DQ Calibration (LPDDR2)

The following steps should be executed:

1. Precharge all active banks (can be done through MDSCR) as required by the standard.
2. Enter the DDR device into MPR/DQ calibration mode through MRS/MRW commands.
3. Configure the MMDC to work with MPR/DQ calibration mode by asserting MPPDCMPR2[MPR\_CMP].
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (MPRDDLCTL[RD\_DL\_ABS\_OFFSET#]) will place the read DQS somewhere inside the read DQ window.
5. Start the calibration process by asserting MPRDDLHWCTL[HW\_RD\_DL\_EN].

### 32.11.4.1.2 Hardware (automatic) Calibration with pre-defined value

In case pre-defined mode is used, i.e. MPPDCMPR2[MPR\_CMP] is cleared, then the following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required by the standard.
2. Configure the pre-defined value, which reflects the value that will be written and compared through the read calibration, to MPPDCMPR1[PDV1, PDV2]
3. Issue write access to the external DDR device by setting MPSWDAR0[SW\_DUMMY\_WR] = 1 (MMDC will generate internally write access without intervention of the system towards bank 0, row 0, column 0)
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. MPRDDLCTL[RD\_DL\_ABS\_OFFSET#] ) will place the read DQS somewhere inside the read DQ window
5. Start the calibration process by asserting MPRDDLHWCTL[HW\_RD\_DL\_EN]

The following steps will be executed automatically by the MMDC for both modes (MPR and Pre-defined value):

6. MMDC waits till the read delay-line is updated with the absolute delay value for all bytes at MPRDDLCTL[RD\_DL\_ABS\_OFFSET#] and also satisfying the Tmod + 4 requirement
7. MMDC drives read command to the external DDR devices and waits 16 or 32 cycles (according to MPRDDLHWCTL[HW\_RD\_DL\_CMP\_CYC]) assuming that the data has arrived from the DDR device.

8. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the initial read DQS isn't inside the read DQ window and the MMDC generates an error for the associated byte at MPRDDLHWCTL[HW\_RD\_DL\_ERR#] . If the comparison passes then MMDC advances to next step.
9. MMDC resets the rd fifo (to the inverted pre-defined/MPR value) and it's pointers by setting MPDGCTRL[RST\_RD\_FIFO] = 1
10. MMDC decrements the read delay line absolute offset of each byte by 1 (i.e. MPRDDLCTL[RD\_DL\_ABS\_OFFSET#] ) and issue measurement process of the read delay-line to update itself with the new value.
11. MMDC drives read command to the DDR external devices and waits 16 or 32 cycles (according to MPRDDLHWCTL[HW\_RD\_DL\_CMP\_CYC]) assuming that the data has arrived from the DDR device
12. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the low read boundary of the associated byte for each byte at MPRDDLHWST0/1[HW\_RD\_DL\_LOW#] . If the comparison passes then MMDC repeats steps 9-11. If all read data comparisons fail then the MMDC advances to the next step
13. The MMDC start seeking the upper boundary and sets the read delay line absolute offset of each byte to the initial value + 1 as determined at step 4 and issue measurement process of the read delay-line to update itself with the new value
14. MMDC resets the rd fifo (to the inverted pre-defined value) and it's pointers by setting MPDGCTRL[RST\_RD\_FIFO] = 1
15. MMDC drives read command to the DDR external devices and waits 16 or 32 cycles (according to MPRDDLHWCTL[HW\_RD\_DL\_CMP\_CYC]) assuming that the data has arrived from the DDR device
16. MMDC compares the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the upper read boundary of the associated byte for each byte at MPRDDLHWST0/1[HW\_RD\_DL\_UP#] . If the comparison passes then MMDC increments the read delay line absolute offset of each byte by 1 (i.e. MPRDDLCTL[RD\_DL\_ABS\_OFFSET#] ) and issue measurement process of the read delay-line to update itself with the new value.
17. If all read data comparisons fail then the MMDC advances to the next step. otherwise, MMDC repeats steps 14-16.
18. After the MMDC finds the window boundary (lower and upper) of each read data byte then it stores the average between lower and upper boundaries at the associated MPRDDLCTL[RD\_DL\_ABS\_OFFSET#] and issue measurement process of the read delay-line to update itself with the new value.

19. MMDC indicates that the read data calibration had finished by setting `MPRDDLHWCTL[HW_RD_DL_EN] = 0`
20. Exit the DDR device from MPR/DQ calibration mode through MRS/MRW commands

### 32.11.4.2 SW Read Calibration

- There are two modes of operations:
- Calibration with the MPR (Multi Purpose Register)/DQ calibration(LPDDR2)
- Calibration with MMDC pre-defined values

#### 32.11.4.2.1 Calibration with MPR(DDR3)/DQ calibration(LPDDR2)

The following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required by the standard.
2. Enter the DDR device into MPR/DQ calibration mode through MRS/MRW commands
3. Configure the MMDC to work with MPR/DQ calibration mode by asserting `MPPDCMPR2[MPR_CMP]`
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. `MPRDDLCTL[RD_DL_ABS_OFFSET#]` ) will place the read DQS somewhere inside the read DQ window

#### 32.11.4.2.2 Calibration with pre-defined value

In case pre-defined mode is used, i.e. `MPPDCMPR2[MPR_CMP]` is cleared, then the following steps should be executed:

1. Precharge all active banks (Can be done through MDSCR) as required by the standard.
2. Configure the pre-defined value, which reflects the value that will be written and compared through the read calibration, to `MPPDCMPR1[PDV1, PDV2]`
3. Issue write access (with any legal DDR address) to external DDR device.
4. Make sure that the initial value that is configured in the read delay line absolute offset of each byte (i.e. `MPRDDLCTL[RD_DL_ABS_OFFSET#]` ) will place the read DQS somewhere inside the read DQ window

The following steps will be executed manually by SW for both modes (MPR/DQ calibration and Pre-defined value):

5. Force the delay line to measure itself and to issue the requested read delay by configuring `MPMUR[FRC_MSR] = 1`
6. Wait 16 DDR cycles till the read delay-line is updated with the absolute delay value for all bytes
7. Issue read command (with any legal DDR address) from the external DDR device
8. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the initial read DQS isn't inside the read DQ window. If the comparison passes then advance to next step.
9. Reset the rd fifo (to the inverted pre-defined/MPR value) and it's pointers by setting `MPDGCTRL[RST_RD_FIFO] = 1`
10. Decrement the read delay line absolute offset of each byte by 1 (i.e. `MPRDDLCTL[RD_DL_ABS_OFFSET#]` )
11. Force the delay line to measure itself and to issue the requested read delay by configuring `MPMUR[FRC_MSR] = 1`
12. Issue read command (with the legal DDR address chosen in step 7) from the external DDR device and waits 16 or 32 cycles (according to `MPRDDLHWCTL[HW_RD_DL_CMP_CYC]`) assuming that the data has arrived from the DDR device
13. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed to store the low read boundary of the associated byte at of each byte . If the comparison passes then repeat steps 9-12. If all read data comparisons fail then advance to the next step.
14. Start seeking the upper boundary and set the read delay line absolute offset of each byte to the initial value + 1 as determined at step 4
15. Force the delay line to measure itself and to issue the requested read delay by configuring `MPMUR[FRC_MSR] = 1`
16. Resets the rd fifo (to the inverted pre-defined/MPR value) and it's pointers by setting `MPDGCTRL[RST_RD_FIFO] = 1`
17. Issue read command (with the legal DDR address chosen in step 7) from the external DDR device
18. Compare the read data byte to the associated byte in the pre-defined/MPR value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed to store the upper read boundary of the associated byte at of each byte. If the comparison passes then increment the read delay line absolute offset of each byte by 1 (i.e. `MPRDDLCTL[RD_DL_ABS_OFFSET#]` )
19. Force the delay line to measure itself and to issue the requested read delay by configuring `MPMUR[FRC_MSR] = 1`
20. If all read data comparisons fail then advance to the next step, else repeat steps 16-19

21. After finding the window boundary (lower and upper) of each read data byte then calculate the average between lower and upper boundaries and store the associated average at MPRDDLCTL[RD\_DL\_ABS\_OFFSET#]
22. Force the delay line to measure itself and to issue the requested read delay by configuring MPMUR[FRC\_MSR] = 1
23. Exit the DDR device from MPR/DQ calibration mode through MRS/MRW commands.

## 32.11.5 Write Calibration

The write calibration is used to adjust the write DQS with write data byte. It is assumed that the read calibration process is completed prior to the write calibration.

### 32.11.5.1 HW (automatic) Write Calibration

The following steps should be executed:

1. Make sure that the initial value that is configured in the write delay line absolute offset of each byte (i.e. MPWRDLCTL[WR\_DL\_ABS\_OFFSET#] ) will place the write DQS somewhere inside the write DQ window
2. Configure the pre-defined value, which reflects the value that will be written and compared through the write calibration, to MPPDCMPR1[PDV1, PDV2]
3. Assert MPWRDLHWCTL0[HW\_WR\_DL\_EN]

The following steps will be executed automatically:

4. MMDC waits till the write delay-line is updated with the absolute delay value for all bytes at MPWRDCTL[WR\_DL\_ABS\_OFFSET#]
5. MMDC drives write command to the external DDR devices (to bank 0 address 0) and waits 16 or 32 cycles (according to MPWRDLHWCTL[HW\_WR\_DL\_CMP\_CYC]) assuming that the data has arrived to the DDR device.
6. MMDC drives read command to the same address from the external DDR
7. MMDC compares the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the initial write DQS isn't inside the write DQ window and the MMDC generates an error for the associated byte at MPWRDLHWCTL[HW\_WR\_DL\_ERR#] . If the comparison passes then MMDC advances to next step.
8. MMDC resets the rd fifo (to the inverted pre-defined value) and it's pointers by setting MPDGCTRL[RST\_RD\_FIFO] = 1

9. MMDC decrements the write delay line absolute offset of each byte by 1 (i.e. `MPWRDLCTL[WR_DL_ABS_OFFSET#]` ) and issue measurement process of the write delay-line to update itself with the new value.
10. MMDC drives write command to the external DDR devices (to bank 0 address 0) and waits 16 or 32 cycles (according to `MPWRDLHWCTL[HW_WR_DL_CMP_CYC]`) assuming that the data has arrived to the DDR device
11. MMDC drives read command to the same address from the external DDR
12. MMDC compares the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the low write boundary of the associated byte of each byte at `MPWRDLHWST0/1[HW_WR_DL_LOW#]` . If the comparison passes then MMDC repeats steps 8-11. If all data comparisons fail then the MMDC advances to the next step
13. The MMDC start seeking the upper boundary and sets the write delay line absolute offset of each byte to the initial value + 1 as determined at step 4 and issue measurement process of the write delay-line to update itself with the new value
14. MMDC resets the rd fifo (to the inverted pre-defined value) and its pointers by setting `MPDGCTRL[RST_RD_FIFO] = 1`
15. MMDC drives write command to the external DDR devices (to bank 0 address 0) and waits 16 or 32 cycles (according to `MPWRDLHWCTL[HW_WR_DL_CMP_CYC]`) assuming that the data has arrived to the DDR device.
16. MMDC drives read command to the same address from the external DDR
17. MMDC compares the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it stores the upper write boundary of the associated byte of each byte at `MPWRDLHWST0/1[HW_WR_DL_UP#]` . If the comparison passes then MMDC increments the write delay line absolute offset of each byte by 1 (i.e. `MPWRDLCTL[WR_DL_ABS_OFFSET#]` ) and issue measurement process of the write delay-line to update itself with the new value.
18. MMDC repeats steps 14-17. If all data comparisons fail then the MMDC advances to the next step
19. .After the MMDC finds the window boundary (lower and upper) of each write data byte then it stores the average between lower and upper boundaries at the associated `MPWRDLCTL[WR_DL_ABS_OFFSET#]` and issue measurement process of the write delay-line to update itself with the new value.
20. MMDC indicates that the write data calibration had finished by setting `MPWRDLHWCTL[HW_WR_DL_EN] = 0`

### 32.11.5.2 SW Write Calibration

The following steps should be executed:

#### NOTE

It is recommended to perform the write calibration using the HW method. The SW method is provided for debug purposes only.

1. Make sure that the initial value that is configured in the write delay line absolute offset of each byte (i.e. `MPWRDLCTL[WR_DL_ABS_OFFSET#]` ) will place the write DQS somewhere inside the write DQ window
2. Configure the pre-defined value, which reflects the value that will be written and compared through the write calibration, to `MPPDCMPR1[PDV1, PDV2]`
3. Force the delay line to measure itself and to issue the requested write delay by configuring `MPMUR[FRC_MSR] = 1`
4. Wait 16 DDR cycles till the write delay-line is updated with the absolute delay value for all bytes
5. Issue write command to any legal DDR address of the external DDR device
6. Issue read command, to the address written previously, from the external DDR device
7. Compare the read data byte to the associated byte in the pre-defined value for all bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it indicates that the initial write DQS isn't inside the write DQ window. If the comparison passes then advance to next step.
8. MMDC resets the rd fifo (to the inverted pre-defined value) and it's pointers by setting `MPDGCTRL[RST_RD_FIFO] = 1`
9. Decrement the write delay line absolute offset of each byte by 1 (i.e. `MPWRDLCTL[WR_DL_ABS_OFFSET#]` )
10. Force the delay line to measure itself and to issue the requested write delay by configuring `MPMUR[FRC_MSR] = 1`
11. Issue write command to any legal DDR address of the external DDR device
12. Issue read command, to the address written previously, from the external DDR device
13. Compare the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed to store the low write boundary of the associated byte of each byte at `MPWRDLHWST0/1[HW_WR_DL_LOW#]` . If the comparison passes then repeat steps 8-12. If all data comparisons fail then advance to the next step.
14. Start seeking the upper boundary and set the write delay line absolute offset of each byte to the initial value + 1
15. Force the delay line to measure itself and to issue the requested write delay by configuring `MPMUR[FRC_MSR] = 1`

16. Reset the rd fifo (to the inverted pre-defined value) and it's pointers by setting `MPDGCTRL[RST_RD_FIFO] = 1`
17. Issue write command to any legal DDR address of the external DDR device
18. Issue read command, to the address written previously, from the external DDR device
19. Compare the read data byte to the associated byte in the pre-defined value for all the bytes in the DDR burst (burst length 4 or 8). If the comparison fails then it is needed to store the upper write boundary of the associated byte of each byte at `MPWRDLHWST0/1[HW_WR_DL_UP#]`. If the comparison passes then increment the write delay line absolute offset of each byte by 1.
20. Force the delay line to measure itself and to issue the requested write delay by configuring `MPMUR[FRC_MSR] = 1`
21. If all read data comparisons fail then advance to the next step else repeat steps 16-20.
22. After finding the window boundary (lower and upper) of each write data byte then calculate the average between lower and upper boundaries and store the associated average at `MPWRDLCTL[WR_DL_ABS_OFFSET#]`
23. Force the delay line to measure itself and to issue the requested write delay by configuring `MPMUR[FRC_MSR] = 1`

### 32.11.6 Write leveling Calibration

The write leveling calibration can generate a delay between the clock and the associate DQS of up to 3 cycles as following:  $(WL\_DL\_ABS\_OFFSET/256 * cycle) + (WL\_HC\_DEL * half\ cycle) + (WL\_CYC\_DEL * cycle)$ .

Write leveling calibration can be executed automatically(HW) or manually (SW).

The automatic calibration process can only detect the optimal DQS to clock delay to within 1 cycle. In extreme cases in which the DDR3 memory is placed far from the microcontroller (long address/command/clock trace lengths), the skew between the DQS and clock may exceed 1 cycle. If this is the case, it is the user's responsibility to both understand that their design causes the DQS to clock skew to exceed 1 cycle and to indicate this manually in the `MPWLDECTRL0/1[WL_CYC_DEL#]`. It is highly recommended to keep the DDR3 memory as close to the microcontroller as possible, especially in embedded system designs. When using fly-by topology, the user should calculate the PCB flight time of the clock signal to the furthest placed DDR3 memory to ensure less than 1 cycle skew between DQS and clock.

#### NOTE

In LPDDR2 mode Write-leveling calibration should be disabled.

In DDR3\_x64 mode activation of the calibration is done by setting MPWLGCR[HW\_WL\_EN] at address 0xBASE1\_0808

### NOTE

It is essential to route the first bit in each data byte group (D0, D8, D16, D24, D32, D40, D48, D56) from the DDR3 memory to the same data bus bits on the controller. The DDR3 memory outputs the state of the DRAM clock during the write leveling calibration. If any of these are not routed properly, the controller will have no information regarding the state of the DRAM clock during calibration. In previous designs in which write leveling calibration was not performed, the board designer would often swap data bits within each byte group to make the data bus routing cleaner and less susceptible to noise and impedance mismatch. This can still be done with DDR3 so long as the requirement of properly routing D0, D8, D16, D24, D32, D40, D48, D56 is maintained.

### 32.11.6.1 Hardware Write Leveling Calibration

The following steps should be executed:

1. Configure the external DDR device to enter write leveling mode through MRS command
2. Activate the DQS output enable by setting MDSCR[WL\_EN]
3. Active automatic calibration by setting MPWLGCR[HW\_WL\_EN]

The following steps will be executed automatically by the MMDC:

4. MMDC enters write leveling mode, counts 25 + 15 cycles and drives the DQS pads as output while the DQ pads will remain inputs. In parallel the MMDC configures the write leveling delay line to "0" (i.e. MPWLDECTRL0[WL\_DL\_ABS\_OFFSET#] = 0) and issue measurement process of the writ-leveling delay-line to update itself with the new value
5. MMDC drives one DQS pulse to the DDR external device
6. MMDC waits 16 cycles (to guarantee that the DQ prime data is stable) and samples the associated prime DQ bit (for example for DQS1 the MMDC samples DQ[8])
7. MMDC increments the write leveling delay line by 1/8 cycle and perform measurement process in order to load the updated value to the associated delay-line
8. MMDC repeats steps 5-7 till the write leveling delay is 1 cycle

9. MMDC checks the 8 bit prime DQ results for each DQS and finds the first transition from 0 to 1. If no transition is found then the MMDC indicates an error at MPWLGCR[HW\_WL\_ERR#]
10. MMDC stores the value that issues the last "0" on the prime DQ before the transition and loads it to the write leveling delay-line. The MMDC initiates a fine-tune process by incrementing the delay-line values by 1 step (which is 1/256 part of a cycle) till detecting the most accurate transition from 0 to 1
11. Upon completion of this process the MMDC de-asserts the MPWLGCR[HW\_WL\_EN] and update the most accurate value of the delay-line at the associated MPWLDECTRL#[WL\_DL\_ABS\_OFFSET#]
12. MMDC perform measurement process in order to load the most accurate value to the associated delay-line
13. User should issue MRS command to exit write leveling mode
14. The user should read the results of the associated delay-line at MPWLDECTRL#[WL\_DL\_ABS\_OFFSET#] and in case the user estimates that the reasonable delay may be above 1 cycle then the user should indicate it at MPWLDECTRL#[WL\_CYC\_DEL#]. Moreover the user should indicate it in MDMISC[WALAT] field. For example, if the result of the write leveling calibration is 100/256 parts of a cycle, but the user estimates that the delay is above 2 cycles then MPWLDECTRL#[WL\_CYC\_DEL#] should be configured to 2, so the total delay will be 2 and 100/256 parts of a cycle
15. Return the DQS output enable to functional mode by deasserting MDSCR[WL\_EN]

### 32.11.6.2 SW Write Leveling Calibration

The following steps should be executed:

#### NOTE

It is recommended to perform the write calibration using the HW method. The SW method is provided for debug purposes only.

1. Configure the external DDR device to enter write leveling mode through MRS command
2. Activate the DQS output enable by setting MDSCR[WL\_EN]
3. Set the write-leveling delay-line offset to "0" by configuring MPWLDECTRL0[WL\_DL\_ABS\_OFFSET#] = 0
4. Force the delay line to measure itself and to issue the requested write-leveling delay by configuring MPMUR[FRC\_MSR] = 1
5. Activate SW write-leveling calibration and issue one DQS pulse by setting MPWLGCR[SW\_WL\_EN] = 1 together with MPWLGCR[SW\_WL\_CNT\_EN] = 1

6. Issue an IP read command from MPWLGCR. If MPWLGCR[SW\_WL\_EN] = 0 then the SW write-leveling result is valid at MPWLGCR[WL\_SW\_RES#].
7. Increment the write leveling delay line by 1/8 cycle (i.e add 0x20 to {MPWLDECTRL0[WL\_HC\_DEL#],MPWLDECTRL0[WL\_DL\_ABS\_OFFSET#]})
8. Force the delay line to measure itself and to issue the requested write-leveling delay by configuring MPMUR[FRC\_MSR] = 1
9. Activate SW write-leveling calibration and issue one DQS pulse by setting MPWLGCR[SW\_WL\_EN] = 1
10. Repeat steps 6-9 till the edge of CK was detected (i.e the write-leveling result switched from "0" to "1")
11. Store the value that issues the last "0" on the prime DQ before the transition and load it to the write leveling delay-line and start fine tuning process to detect the exact switch from "0" to "1"
12. Force the delay line to measure itself and to issue the requested write-leveling delay by configuring MPMUR[FRC\_MSR] = 1
13. Activate SW write-leveling calibration and issue one DQS pulse by setting MPWLGCR[SW\_WL\_EN] = 1
14. Issue an IP read command from MPWLGCR. If MPWLGCR[SW\_WL\_EN] = 0 then the SW write-leveling result is valid at MPWLGCR[WL\_SW\_RES#].
15. Increment the write leveling delay line by 1 step (i.e add 0x01 to MPWLDECTRL0[WL\_DL\_ABS\_OFFSET#])
16. Force the delay line to measure itself and to issue the requested write-leveling delay by configuring MPMUR[FRC\_MSR] = 1
17. Issue an IP read command from MPWLGCR. If MPWLGCR[SW\_WL\_EN] = 0 then the SW write-leveling result is valid at MPWLGCR[WL\_SW\_RES#].
18. Activate SW write-leveling calibration and issue one DQS pulse by setting MPWLGCR[SW\_WL\_EN] = 1
19. Repeat steps 15-18 till the exact edge of CK was detected (i.e the write-leveling result switched from "0" to "1")
20. Issue MRS command to exit write leveling mode
21. Return the DQS output enable to functional mode by deasserting MDSCR[WL\_EN]

### 32.11.7 Write fine tuning

Write fine tuning is an additional circuit that provides the ability to fine tune the timing of each dq/dm bits (relative to dqs) by up to +/-100 ps.

This is done by reducing the delay between the `wl_dqs` by 100 ps and adding a configurable delay of up to 200 ps (6 delay units of around 30-35 ps each) for each DQ/DM output. The delay can be configured independently for each DQ/DM. The calibration of this mechanism can be done only by writing & reading data from the memory. Controlled by register `MPWRDQBY#DL`.

### 32.11.8 Read fine tuning

Read fine tuning is an additional circuit that provides the ability to fine tune the timing of each coming dq bits (relative to coming dqs) by up to +/-100 ps.

This is done by reducing the delay between the incoming `rd_dqs` by 100 ps and adding a configurable delay of up to 200 ps (6 delay units of around 30-35 ps each) for each DQ input. The delay can be configured independently for each DQ. The calibration of this mechanism can be done only by writing & reading data from the memory. Controlled by register `MPRDDQBY#DL`.

## 32.12 MMDC Memory Map/Register Definition

**MMDC\_MDCTL field descriptions**

Field	Description
31 SDE_0	MMDC Enable CS0. This bit enables/disables accesses from the MMDC toward Chip Select 0. The reset value of this bit is "0" (i.e No clocks and clock enable will be driven to the memory).  At the enabling point the MMDC will perform an initialization process (including a delay on RESET and/or CKE) for both chip selects. The initialization length depends on the configured memory type.  0 Disabled 1 Enabled
30 SDE_1	MMDC Enable CS1. This bit enables/disables accesses from the MMDC toward Chip Select 1. The reset value of this bit is "0" (i.e No clocks and clock enable will be driven to the memory).  At the enabling point the MMDC will perform an initialization process (including a delay on RESET and/or CKE) for both chip selects. The initialization length depends on the configured memory type.  0 Disabled 1 Enabled

*Table continues on the next page...*

### MMDC\_MDCTL field descriptions (continued)

Field	Description
29–27 Reserved	This read-only field is reserved and always has the value 0.
26–24 ROW	<p>Row Address Width. This field specifies the number of row addresses used by the memory array. It will affect the way an incoming address will be decoded.</p> <p>Settings 110-111 are reserved</p> <p>000 11 bits Row  001 12 bits Row  010 13 bits Row  011 14 bits Row  100 15 bits Row  101 16 bits Row</p>
23 Reserved	This read-only field is reserved and always has the value 0.
22–20 COL	<p>Column Address Width. This field specifies the number of column addresses used by the memory array. It will determine how an incoming address will be decoded.</p> <p>0x0 9 bits column  0x1 10 bits column  0x2 11 bits column  0x3 8 bits column  0x4 12 bits column  0x5-0xF Reserved</p>
19 BL	<p>Burst Length. This field determines the burst length of the DDR device.</p> <p>In LPDDR2 mode the MMDC supports burst length 4.</p> <p>In DDR3 mode the MMDC supports burst length 8.</p> <p>0 Burst Length 4 is used  1 Burst Length 8 is used</p>
18 Reserved	This read-only field is reserved and always has the value 0.
17–16 DSIZ	<p>DDR data bus size. This field determines the size of the data bus of the DDR memory</p> <p>0 16-bit data bus  1 32-bit data bus  —  —  2-3 Reserved</p>
15–0 Reserved	This read-only field is reserved and always has the value 0.

## 32.12.2 MMDC Core Power Down Control Register (MMDC\_MDPDC)

Table 32-13. PRCT field encoding

PRCT[2:0]	Precharge Timer
000	Disabled (Bit field reset value)
001	2 clocks
010	4 clocks
011	8 clocks
100	16 clocks
101	32 clocks
110	64 clocks
111	128 clocks

Table 32-14. PWDT field encoding

PWDT[3:0]	Power Down Time-out
0000	Disabled (bit field reset value)
0001	16 cycles
0010	32 cycles
0011	64 cycles
0100	128 cycles
0101	256 cycles
0110	512 cycles
0111	1024 cycles
1000	2048 cycles
1001	4096 cycles
1010	8196 cycles
1011	16384 cycles
1100	32768 cycles
1101-1111	Reserved

### MMDC\_MDPDC field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–28 PRCT_1	Precharge Timer - Chip Select 1. This field determines the amount of idle cycle for which chip select 1 will be automatically precharged. The amount of cycles are determined according to the PRCT Field Encoding table above.
27 Reserved	This read-only field is reserved and always has the value 0.
26–24 PRCT_0	Precharge Timer - Chip Select 0. This field determines the amount of idle cycle for which chip select 0 will be automatically precharged. The amount of cycles are determined according to the table below.
23–19 Reserved	This read-only field is reserved and always has the value 0.
18–16 tCKE	CKE minimum pulse width. This field determines the minimum pulse width of CKE.  0x0 1 cycle 0x1 2 cycles 0x6 7 cycles 0x7 8 cycles
15–12 PWDT_1	Power Down Timer - Chip Select 1. This field determines the amount of idle cycle for which chip select 1 will be automatically get into precharge/active power down. The amount of cycles are determined according to the PWDT Field Encoding table above.
11–8 PWDT_0	Power Down Timer - Chip Select 0. This field determines the amount of idle cycle for which chip select 0 will be automatically get into precharge/active power down. The amount of cycles are determined according to the PWDT Field Encoding table above.
7 SLOW_PD	Slow/fast power down. In DDR3 mode this field is referred to slow precharge power-down. In LPDDR2 mode this field is not relevant.  <b>NOTE:</b> Memory should be configured the same.  0 Fast mode. 1 Slow mode.
6 BOTH_CS_PD	Parallel power down entry to both chip selects. When power down timer is used for both chip-selects (i.e PWDT_0 and PWDT1 don't equal "0" ), then if this bit is enabled, the MMDC will enter power down only if the amount of idle cycles of both chip selects was obtained.

Table continues on the next page...

## MMDC\_MDPDC field descriptions (continued)

Field	Description
	0 Each chip select can enter power down independently according to its configuration. 1 Chip selects can enter power down only if the amount of idle cycles of both chip selects was obtained.
5–3 tCKSRX	Valid clock cycles before self-refresh exit. This field determines the amount of clock cycles before self-refresh exit  0x0 0 cycle 0x1 1 cycles 0x6 6 cycles 0x7 7 cycles
2–0 tCKSRE	Valid clock cycles after self-refresh entry. This field determines the amount of clock cycles after self-refresh entry  0x0 0 cycle 0x1 1 cycles 0x6 6cycles 0x7 7cycles

### 32.12.3 MMDC Core ODT Timing Control Register (MMDC\_MDOTC)

For further information see [ODT Configuration](#).

Address: 21B\_0000h base + 8h offset = 21B\_0008h

## MMDC\_MDOTC field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value 0.
29–27 tAOFPD	Asynchronous RTT turn-off delay (power down with DLL frozen). This field determines the time between termination circuit starts to turn off the ODT resistance till termination has reached high impedance.  This field is not relevant in LPDDR2 mode.  0x0 1 cycle

Table continues on the next page...

### MMDC\_MDOTC field descriptions (continued)

Field	Description
	0x1 2 cycles 0x6 7 cycles 0x7 8 cycles
26–24 tAONPD	Asynchronous RTT turn-on delay (power down with DLL frozen). This field determines the time between termination circuit gets out of high impedance and begins to turn on till ODT resistance are fully on. This field is not relevant in LPDDR2 mode. 0x0 1 cycle 0x1 2 cycles 0x6 7 cycles 0x7 8 cycles
23–20 tANPD	Asynchronous ODT to power down entry delay. In DDR3 should be set to tCWL-1 This field is not relevant in LPDDR2 mode. 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF 16 clocks
19–16 tAXPD	Asynchronous ODT to power down exit delay. In DDR3 should be set to tCWL-1 This field is not relevant in LPDDR2 mode. 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF 16 clocks
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 tODTLon	ODT turn on latency. This field determines the delay between ODT signal and the associated RTT, where according to JEDEC standard it equals WL(write latency) - 2. Therefore, the value that is configured to tODTLon field should correspond the value that is configured to MDCGFG1[tCWL] In LPDDR2 this field is not relevant. 0x0 - 0x1 Reserved 0x2 2 cycles 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 Reserved
11–9 Reserved	This read-only field is reserved and always has the value 0.
8–4 tODT_idle_off	ODT turn off latency. This field determines the Idle period before turning memory ODT off. This field is not relevant in LPDDR2 mode. 0x0 0 cycle (turned off at the earliest possible time)

Table continues on the next page...

**MMDC\_MDOTC field descriptions (continued)**

Field	Description
	0x1 1 cycle 0x2 2 cycles 0x1E 30 cycles 0x1F 31 cycles
3–0 Reserved	This read-only field is reserved and always has the value 0.

## 32.12.4 MMDC Core Timing Configuration Register 0 (MMDC\_MDCFG0)

Address: 21B\_0000h base + Ch offset = 21B\_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**MMDC\_MDCFG0 field descriptions**

Field	Description
31–24 tRFC	Refresh command to Active or Refresh command time.  See DDR3 SDRAM Specification JESD79-3E (July 2010) and LPDDR2 SDRAM Specification JESD209-2B (February 2010) for a detailed description of this parameter.  0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xFE 255 clocks 0xFF 256 clocks
23–16 tXS	Exit self refresh to non READ command. In LPDDR2 it is called tXSR, self-refresh exit to next valid command delay.  See DDR3 SDRAM Specification JESD79-3E (July 2010) and LPDDR2 SDRAM Specification JESD209-2B (February 2010) for a detailed description of this parameter.  0x0 - 0x15 reserved 0x16 23 clocks 0x17 24 clocks 0xFE 255 clocks 0xFF 256 clocks
15–13 tXP	Exit power down with DLL-on to any valid command. Exit power down with DLL-frozen to commands not requiring a locked DLL.  In LPDDR2 mode this field is referred to Exit power-down to next valid command delay.  See DDR3 SDRAM Specification JESD79-3E (July 2010) and LPDDR2 SDRAM Specification JESD209-2B (February 2010) for a detailed description of this parameter.

*Table continues on the next page...*

### MMDC\_MDCFG0 field descriptions (continued)

Field	Description
	0x0 1 cycle 0x1 2 cycles 0x6 7 cycles 0x7 8 cycles
12–9 tXPDLL	Exit precharge power down with DLL frozen to commands requiring DLL. This field is not relevant in LPDDR2 mode. See DDR3 SDRAM Specification JESD79-3E (July 2010) and LPDDR2 SDRAM Specification JESD209-2B (February 2010) for a detailed description of this parameter. 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF 16 clocks
8–4 tFAW	Four Active Window (all banks). See DDR3 SDRAM Specification JESD79-3E (July 2010) and LPDDR2 SDRAM Specification JESD209-2B (February 2010) for a detailed description of this parameter. 0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0x1E 31 clocks 0x1F 32 clocks
3–0 tCL	CAS Read Latency. In DDR3 mode this field is referred to CL. In LPDDR2 mode this field is referred to RL. <b>NOTE:</b> In LPDDR2 mode only the RL/WL pairs are allowed as specified in MR2 register See DDR3 SDRAM Specification JESD79-3E (July 2010) and LPDDR2 SDRAM Specification JESD209-2B (February 2010) for a detailed description of this parameter. 0x0 3 cycles 0x1 4 cycles 0x2 5 cycles 0x3 6 cycles 0x4 7 cycles 0x5 8 cycles 0x6 9 cycles 0x7 10 cycles 0x8 11 cycles 0x9 - 0xF Reserved

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	0			BL_ON	LPDDR2_S2	MIF3_MODE			RALAT			DDR_4_BANK	DDR_TYPE		0	RST	0
W																	
Reset	0	0	0	1	0	1	1	0	0	0	0	0	0	0	0	0	

**MMDC\_MDMISC field descriptions**

Field	Description
31 CS0_RDY	External status device on CS0. This is a read-only status bit, that indicates whether the external memory is in wake-up period.  0 Device in wake-up period. 1 Device is ready for initialization.
30 CS1_RDY	External status device on CS1. This is a read-only status bit, that indicates whether the external memory is in wake-up period.  0 Device in wake-up period. 1 Device is ready for initialization.

*Table continues on the next page...*

## MMDC\_MDMISC field descriptions (continued)

Field	Description
29–22 Reserved	This read-only field is reserved and always has the value 0.
21 CK1_GATING	Gating the secondary DDR clock. When this bit is asserted then the MMDC will disable the secondary DDR clock  0 MMDC drives two clocks toward the DDR memory 1 MMDC drives only one clock toward the DDR memory (CK0)
20 CALIB_PER_CS	Number of chip-select for calibration process. This bit determines the chip-select index that the associated calibration is targetted to. Relevant for read, write, write leveling and read DQS gating calibrations  0 Calibration is targetted to CS0 1 Calibration is targetted to CS1
19 ADDR_MIRROR	Address mirroring. <b>NOTE:</b> This feature is not supported for LPDDR2 memories. But only for DDR3 memories. For further information see <a href="#">Address mirroring</a> .  0 Address mirroring disabled. 1 Address mirroring enabled.
18 LHD	Latency hiding disable.  This is a debug feature. When set to "1" the MMDC will handle one read/write access at a time. Meaning that the MMDC pipe-line will be limited to 1 open access (next AXI address phase will be acknowledged if the current AXI data phase had finished)  0 Latency hiding on. 1 Latency hiding disable.
17–16 WALAT	Write Additional latency.  In case the write-leveling calibration process indicates a delay around half cycle (between CK and the associated DQS) then this field must be configured accordingly.  This field will add delay on the oboe I/O control, which will compensate on the additional write leveling delay on DQS and prevent the DQS from being cropped.  0x0 No additional latency required. 0x1 1 cycle additional delay 0x2 2 cycles additional delay 0x3 3 cycles additional delay
15–13 Reserved	This read-only field is reserved and always has the value 0.
12 BI_ON	Bank Interleaving On. This bit controls the organization of the bank, row and column address bits. For further information see <a href="#">Address decoding</a> .  0 Banks are not interleaved, and address will be decoded as bank-row-column 1 Banks are interleaved, and address will be decoded as row-bank-column
11 LPDDR2_S2	LPDDR2 S2 device type indication.  In case LPDDR2 device is used (DDR_TYPE = 0x1), this bit will indicate whether S2 or S4 device is used.  This bit should be cleared in DDR3 mode

*Table continues on the next page...*

**MMDC\_MDMISC field descriptions (continued)**

Field	Description
	0x0 LPDDR2-S4 device is used. 0x1 LPDDR2-S2 device is used.
10–9 MIF3_MODE	Command prediction working mode. This field determines the level of command prediction that will be used by the MMDC  00 Disable prediction. 01 Enable prediction based on : Valid access on first pipe line stage. 10 Enable prediction based on: Valid access on first pipe line stage, Valid access on axi bus. 11 Enable prediction based on: Valid access on first pipe line stage, Valid access on axi bus, Next miss access from access queue.
8–6 RALAT	Read Additional Latency. This field determines the additional read latency which is added to CAS latency and internal delays for which the MMDC will retrieve the read data from the internal FIFO. This field is used to compensate on board/chip delays.  <b>NOTE:</b> In LPDDR2 mode 2 extra cycles will be added internally in order to compensate tDQSCK delay.  0x0 no additional latency. 0x1 1 cycle additional latency. 0x2 2 cycles additional latency. 0x3 3 cycles additional latency. 0x4 4 cycles additional latency. 0x5 5 cycles additional latency. 0x6 6 cycles additional latency. 0x7 7 cycles additional latency.
5 DDR_4_BANK	Number of banks per DDR device. When this bit is set to "1" then the MMDC will work with DDR device of 4 banks.  0 8 banks device is being used. (Default) 1 4 banks device is being used
4–3 DDR_TYPE	DDR TYPE. This field determines the type of the external DDR device.  0x0 DDR3 device is used. (Default) 0x1 LPDDR2 device is used. — — 0x2 Reserved. 0x3 Reserved.
2 Reserved	This read-only field is reserved and always has the value 0.
1 RST	Software Reset. When this bit is asserted then the internal FSMs and registers of the MMDC will be initialized.  <b>NOTE:</b> This bit once asserted gets deasserted automatically.  0 Do nothing. 1 Assert reset to the MMDC.
0 Reserved	This read-only field is reserved and always has the value 0.

### 32.12.8 MMDC Core Special Command Register (MMDC\_MDSCR)

This register is used to issue special commands manually toward the external DDR device (such as load mode register, manual self refresh, manual precharge and so on). Every write to this register will be interpreted as a command, and a read from this register will show the last command that was executed.

Every write to this register will result in one special command, and the IP bus will assert `ips_xfr_wait` as long as the special command is being carried out.

Address: 21B\_0000h base + 1Ch offset = 21B\_001Ch

MMDC\_MDSCR field descriptions

Field	Description
31–24 CMD_ADDR_ MSB_MR_OP	Command/Address MSB. This field indicates the MSB of the command/Address. In LPDDR2 this field indicates the MRW operand
23–16 CMD_ADDR_ LSB_MR_ADDR	Command/Address LSB. This field indicates the LSB of the command/Address In LPDDR2 this field indicates the MRR/MRW address
15 CON_REQ	<p>Configuration request.</p> <p>When this bit is set then the MMDC will clean the pending AXI accesses and will prevent from further AXI accesses to be acknowledged. This field guarantee safe configuration (or change configuration) of the MMDC while no access is in process and prevents an unexpected behaviour.</p> <p>After setting this bit, it is needed to poll on CON_ACK until it is set to "1". When CON_ACK is asserted then configuration is permitted. After configuration is completed then this bit must be deasserted in order to process further AXI accesses.</p> <p><b>NOTE:</b> This bit is asserted at the end of the reset sequence, meaning that the MMDC is waiting to configure and initialize the external memory before accepting any AXI accesses. Configuration request/acknowledge mechanism should be used for the following procedures: changing of timing parameters , during calibration process or driving commands via MDSCR[CMD]</p>

Table continues on the next page...

### MMDC\_MDSCR field descriptions (continued)

Field	Description
	0 No request to configure MMDC. 1 A request to configure MMDC is valid
14 CON_ACK	Configuration acknowledge. Whenever this bit is set, it is permitted to configure MMDC IP registers. 0 Configuration of MMDC registers is forbidden. 1 Configuration of MMDC registers is permitted.
13–11 Reserved	This read-only field is reserved and always has the value 0.
10 MRR_READ_DATA_VALID	MRR read data valid. This field indicates that read data is valid at MDMRR register This field is relevant only for LPDDR2 mode 0 Cleared upon the assertion of MRR command 1 Set after MRR data is valid and stored at MDMRR register.
9 WL_EN	DQS pads direction. This bit controls the DQS pads direction during write-leveling calibration process. Before starting the write-leveling calibration process this bit should be set to "1". It should be set to "0" when sending write leveling exit command. For further information see <a href="#">Write leveling Calibration</a> . 0 Exit write leveling mode or stay in normal mode. 1 Write leveling entry command was sent.
8–7 Reserved	This read-only field is reserved and always has the value 0.
6–4 CMD	Command. This field contains the command to be executed. This field will be automatically cleared after the command will be send to the DDR memory. 0x0 Normal operation 0x1 Precharge all, command is sent independently of bank status (set correct CMD_CS). Will be issued even if banks are closed. Mainly used for init sequence purpose. 0x2 Auto-Refresh Command (set correct CMD_CS). 0x3 Load Mode Register Command ( DDR3, set correct CMD_CS, CMD_BA, CMD_ADDR_LSB, CMD_ADDR_MSB), MRW Command (LPDDR2, set correct CMD_CS, MR_OP, MR_ADDR) 0x4 ZQ calibration ( DDR3, set correct CMD_CS, {CMD_ADDR_MSB,CMD_ADDR_LSB} = 0x400 or 0x0 ) 0x5 Precharge all, only if banks open (set correct CMD_CS). 0x6 MRR command (LPDDR2, set correct CMD_CS, MR_ADDR) 0x7 Reserved
3 CMD_CS	Chip Select. This field determines which chip select the command is targeted to 0 to Chip-select 0 1 to Chip-select 1
2–0 CMD_BA	Bank Address. This field determines the address of the bank within the selected chip-select where the command is targetted to. 0x0 bank address 0 0x1 bank address 1

Table continues on the next page...

**MMDC\_MDSCR field descriptions (continued)**

Field	Description
0x2	bank address 2
0x7	bank address 7

**32.12.9 MMDC Core Refresh Control Register (MMDC\_MDREF)**

This register determines the refresh scheme that will be executed toward the DDR device. It specifies how often a refresh cycle occurs and how many refresh commands will be executed every refresh cycle.

For further information see [Refresh Scheme](#).

The following tables show examples of possible refresh schemes.

**Table 32-22. Refresh rate example for REF\_SEL = 0**

REFR[2:0]	Number of refresh commands every 64KHz	Average periodic refresh rate (tREFI)	System Refresh period
0x0	1	15.6 $\mu$ s	tRFC
0x1	2	7.8 $\mu$ s	2*tRFC
0x3	4	3.9 $\mu$ s	4*tRFC
0x7	8	1.95 $\mu$ s	8*tRFC

**Table 32-23. Refresh rate example for REF\_SEL = 1**

REFR[2:0]	Number of refresh commands every 32KHz	Average periodic refresh rate (tREFI)	System Refresh period
0x1	2	15.6 $\mu$ s	2*tRFC
0x3	4	7.8 $\mu$ s	4*tRFC
0x7	8	3.9 $\mu$ s	8*tRFC

**Table 32-24. Refresh rate example for REF\_SEL = 2@ 400MHz**

REFR[2:0]	Number of refresh commands every refresh cycle	REF_CNT	Average periodic refresh rate (tREFI)	System Refresh period
0x0	1	0x618	3.9 $\mu$ s	tRFC
0x1	2	0xC30	3.9 $\mu$ s	2*tRFC
0x2	3	0x1248	3.9 $\mu$ s	3*tRFC
0x3	4	0x1860	3.9 $\mu$ s	4*tRFC

Other refresh configurations are also allowed; the configuration values in the tables above are only examples for obtaining the desired average periodic refresh rate.

If the required average periodic refresh rate (tREFI) is kept, all of the rows will be refreshed in every refresh window. Because the memory device issues additional refresh commands for every refresh it receives, the tREFI remains the same across the device, regardless of its number of rows. This is particularly relevant in the tRFC parameter, which becomes bigger as the density increases.

Address: 21B\_0000h base + 20h offset = 21B\_0020h

### MMDC\_MDREF field descriptions

Field	Description
31–16 REF_CNT	Refresh Counter at DDR clock period If REF_SEL equals '2' a refresh cycle will begin every amount of DDR cycles configured in this field.  0x0     Reserved. 0x1     1 cycle. 0xFFFFE 65534 cycles. 0xFFFF 65535 cycles.
15–14 REF_SEL	Refresh Selector. This bit selects the source of the clock that will trigger each refresh cycle:  0     Periodic refresh cycles will be triggered in frequency of 64KHz. 1     Periodic refresh cycles will be triggered in frequency of 32KHz. 2     Periodic refresh cycles will be triggered every amount of cycles that are configured in REF_CNT field. 3     No refresh cycles will be triggered.
13–11 REFR	Refresh Rate. This field determines how many refresh commands will be issued every refresh cycle. After every refresh command the MMDC won't drive any command to the DDR device untill satisfying tRFC period

*Table continues on the next page...*

**MMDC\_MDREF field descriptions (continued)**

Field	Description
	0x0 1 refresh 0x1 2 refreshes 0x2 3 refreshes 0x3 4 refreshes 0x4 5 refreshes 0x5 6 refreshes 0x6 7 refreshes 0x7 8 refreshes
10–1 Reserved	This read-only field is reserved and always has the value 0.
0 START_REF	Manual start of refresh cycle. When this field is set to '1' the MMDC will start a refresh cycle immediately according to number of refresh commands that are configured in 'REFR' field. This bit returns to zero automatically. 0 Do nothing. 1 Start a refresh cycle.

**32.12.10 MMDC Core Read/Write Command Delay Register (MMDC\_MDRWD)**

This register determines the delay between back to back read and write accesses. The register reset values are set to the minimum required value. As the default values are set to achieve optimal results, changing them is discouraged.

Address: 21B\_0000h base + 2Ch offset = 21B\_002Ch

**MMDC\_MDRWD field descriptions**

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28–16 tDAI	Device auto initialization period.(maximum) This field is relevant only to LPDDR2 mode

*Table continues on the next page...*

### MMDC\_MDRWD field descriptions (continued)

Field	Description
	0x0 1 cycle 0xF9F 4000 cycles (Default, JEDEC value for LPDDR2, gives 10us at 400MHz clock). 0x1FFF 8192 cycles
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 RTW_SAME	Read to write delay for the same chip-select. This field controls the delay between read to write commands toward the same chip select. The total delay is calculated according to: $BL/2 + RTW\_SAME + (tCL - tCWL) + RALAT$ 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles (Default) 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles
11–9 WTR_DIFF	Write to read delay for different chip-select. This field controls the delay between write to read commands toward different chip select. The total delay is calculated according to: $BL/2 + WTR\_DIFF + (tCL - tCWL) + RALAT$ 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles 0x3 3 cycles (Default) 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles
8–6 WTW_DIFF	Write to write delay for different chip-select. This field controls the delay between write to write commands toward different chip select. The total delay is calculated according to: $BL/2 + WTW\_DIFF$ 0x0 0 cycle 0x1 1 cycle 0x2 2 cycles 0x3 3 cycles (Default) 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles
5–3 RTW_DIFF	Read to write delay for different chip-select. This field controls the delay between read to write commands toward different chip select. The total delay is calculated according to: $BL/2 + RTW\_DIFF + (tCL - tCWL) + RALAT$ 0x0 0 cycle 0x1 1 cycle

Table continues on the next page...

**MMDC\_MDRWD field descriptions (continued)**

Field	Description
	0x2 2 cycles (Default) 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles
2–0 RTR_DIFF	Read to read delay for different chip-select. This field controls the delay between read to read commands toward different chip select.  The total delay is calculated according to: $BL/2 + RTR\_DIFF$  0x0 0 cycle 0x1 1 cycle 0x2 2 cycles (Default) 0x3 3 cycles 0x4 4 cycles 0x5 5 cycles 0x6 6 cycles 0x7 7 cycles

### 32.12.11 MMDC Core Out of Reset Delays Register (MMDC\_MDOR)

This register defines delays that must be kept when MMDC exits reset.

Address: 21B\_0000h base + 30h offset = 21B\_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	0								tXPR								0		SDE_to_RST						0		RST_to_CKE						
W																																	
Reset	0	0	0	0	0	0	0	0	1	0	0	1	1	1	1	1	0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1	0

**MMDC\_MDOR field descriptions**

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23–16 tXPR	DDR3: CKE HIGH to a valid command.  This field is not relevant in LPDDR2 mode.  DDR3: As defined in timing parameter table.  0x0 Reserved 0x1 2 cycles

*Table continues on the next page...*

### MMDC\_MDOR field descriptions (continued)

Field	Description
	0x2 3 cycles 0xFE 255 cycles 0xFF 256 cycles
15–14 Reserved	This read-only field is reserved and always has the value 0.
13–8 SDE_to_RST	DDR3: Time from SDE enable until DDR reset# is high. In LPDDR2 mode this field is not relevant . <b>NOTE:</b> Each cycle in this field is 15.258 us.  0x0 Reserved 0x1 Reserved 0x2 Reserved 0x3 1 cycles 0x4 2 cycles 0x10 14 cycles (Jedec value for DDR3) - total of 200 us 0x3E 60 cycles 0x3F 61 cycles
7–6 Reserved	This read-only field is reserved and always has the value 0.
5–0 RST_to_CKE	DDR3: Time from SDE enable to CKE rise. In case that DDR reset# is low, will wait until it's high and thenwait this period until rising CKE. (JEDEC value is 500 us) LPDDR2: Idle time ater first CKE assertion. (JEDEC value is 200 us) <b>NOTE:</b> Each cycle in this field is 15.258 us.  0x0 Reserved 0x1 Reserved 0x2 Reserved 0x3 1 cycles 0x10 14 cycles (JEDEC value for LPDDR2) - total of 200 us 0x23 33 cycles (JEDEC value for DDR3) - total of 500 us 0x3E 60 cycles 0x3F 61 cycles

### 32.12.12 MMDC Core MRR Data Register (MMDC\_MDMRR)

This register contains data that was collected after issuing MRR command. The data in this register is valid only when MDSCR[MRR\_READ\_DATA\_VALID] is set to "1".

This register is relevant only in LPDDR2 mode. For further information see [LPDDR2 Refresh Rate Update and Timing Derating](#) .

Address: 21B\_0000h base + 34h offset = 21B\_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	MRR_READ_DATA3								MRR_READ_DATA2								MRR_READ_DATA1								MRR_READ_DATA0

**MMDC\_MDCFG3LP field descriptions**

Field	Description
31–22 Reserved	This read-only field is reserved and always has the value 0.
21–16 RC_LP	Active to Active or Refresh command period (same bank). (This field is valid only for LPDDR2 memories)  0x0    1 clock 0x1    2 clocks 0x2    3 clocks

*Table continues on the next page...*

### MMDC\_MDCFG3LP field descriptions (continued)

Field	Description
	0x3E 63 clocks 0x3F Reserved
15–12 Reserved	This read-only field is reserved and always has the value 0.
11–8 tRCD_LP	Active command to internal read or write delay time (same bank). (This field is valid only for LPDDR2 memories)  0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF Reserved
7–4 tRPpb_LP	Precharge (per bank) command period (same bank). (This field is valid only for LPDDR2 memories)  0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF Reserved
3–0 tRPab_LP	Precharge (all banks) command period. (This field is valid only for LPDDR2 memories)  0x0 1 clock 0x1 2 clocks 0x2 3 clocks 0xE 15 clocks 0xF Reserved

### 32.12.14 MMDC Core MR4 Derating Register (MMDC\_MDMR4)

This register is relevant only for LPDDR2 mode. It is used to dynamically change certain values depending on MR4 read result, which is based on memory temperature sensor result.

Address: 21B\_0000h base + 3Ch offset = 21B\_003Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### MMDC\_MDMR4 field descriptions

Field	Description
31–9 Reserved	This read-only field is reserved and always has the value 0.
8 tRRD_DE	tRRD derating value. 0 Original tRRD is used. 1 tRRD is derated in 1 cycle.
7 tRP_DE	tRP derating value. 0 Original tRP is used. 1 tRP is derated in 1 cycle.
6 tRAS_DE	tRAS derating value. 0 Original tRAS is used. 1 tRAS is derated in 1 cycle.
5 tRC_DE	tRC derating value. 0 Original tRC is used. 1 tRC is derated in 1 cycle.
4 tRCD_DE	tRCD derating value. 0 Original tRCD is used. 1 tRCD is derated in 1 cycle.
3–2 Reserved	This read-only field is reserved and always has the value 0.
1 UPDATE_DE_ACK	Update Derated Values Acknowledge. This read only bit will be cleared upon UPDATE_DE_REQ assertion and will be set after the new values are taken.
0 UPDATE_DE_REQ	Update Derated Values Request. This read modify write field is automatically cleared after the request is issued. 0 Do nothing. 1 Request to update the following values: tRRD, tRCD, tRP, tRC, tRAS and refresh related fields(MDREF register): REF_CNT, REF_SEL, REFR

### 32.12.15 MMDC Core Address Space Partition Register (MMDC\_MDASP)

This register defines the partitioning between chip select 0 and chip select 1. For further information see [Chip select settings](#).

Address: 21B\_0000h base + 40h offset = 21B\_0040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																CS0_END															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1

#### MMDC\_MDASP field descriptions

Field	Description
31–7 Reserved	This read-only field is reserved and always has the value 0.
6–0 CS0_END	CS0_END. Defines the absolute last address associated with CS0 with increments of 256Mb. CS0_END=AXI_ADDRESS[31:25] bits.  000_0000 256Mb 000_0001 512Mb 001_1111 8Gb (1GB) 011_1111 16Gb (2GB) - default 111_1111 32Gb (4GB)

## 32.12.16 MMDC Core AXI Reordering Control Register (MMDC\_MAARCR)

This register determines the values of the weights used for the re-ordering arbitration engine. For further information see [Performance](#).

Address: 21B\_0000h base + 400h offset = 21B\_0400h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ARCR_SEC_ERR_LOCK	ARCR_SEC_ERR_EN	Reserved	ARCR_EXC_ERR_EN	Reserved				ARCR_RCH_EN	Reserved	ARCR_PAG_HIT			Reserved	ARCR_ACC_HIT	
W																
Reset	0	1	0	1	0	0	0	1	0	1	0	0	0	0	1	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved				ARCR_DYN_JMP				ARCR_DYN_MAX				ARCR_GUARD			
W																
Reset	0	0	0	0	0	0	0	1	1	1	1	1	0	0	0	0

**MMDC\_MAARCR field descriptions**

Field	Description
31 ARCR_SEC_ERR_LOCK	Once set, this bit locks ARCR_SEC_ERR_EN and prevents from its updating. This bit can be only cleared by reset Default value is 0x0 - encoding 0 (unlocked) 0 ARCR_SEC_ERR_EN is unlocked, so can be updated any moment 1 ARCR_SEC_ERR_EN is locked, so it can't be updated
30 ARCR_SEC_ERR_EN	This bit defines whether security read/write access violation result in SLV Error response or in OKAY response Default value is 0x1 - encoding 1(response is SLV Error, rresp/bresp=2'b10) 0 security violation results in OKAY response (rresp/bresp=2'b00) 1 security violation results in SLAVE Error response (rresp/bresp=2'b10)

Table continues on the next page...

**MMDC\_MAARCR field descriptions (continued)**

Field	Description
29 -	This field is reserved. Reserved
28 ARCR_EXC_ERR_EN	This bit defines whether exclusive read/write access violation of AXI 6.2.4 rule result in SLV Error response or in OKAY response Default value is 0x1 - encoding 1(response is SLV Error)  0 violation of AXI exclusive rules (6.2.4) result in OKAY response (rresp/bresp=2'b00) 1 violation of AXI exclusive rules (6.2.4) result in SLAVE Error response (rresp/bresp=2'b10)
27–25 -	This field is reserved. Reserved
24 ARCR_RCH_EN	This bit defines whether Real time channel is activated and bypassed all other pending accesses, So accesses with QoS=='F' will be granted the highest priority in the optimization/reordering mechanism Default value is 0x1 - encoding 1 (Enabled)  0 normal prioritization, no bypassing 1 accesses with QoS=='F' bypass the arbitration
23 -	This field is reserved. Reserved
22–20 ARCR_PAG_HIT	ARCR Page Hit Rate. This value will be added by the optimization/reordering mechanism to any pending access that is targeted to an open DDR row. Default value of ARCR_PAG_HIT is 0x00100 - encoding 4.
19 -	This field is reserved. Reserved
18–16 ARCR_ACC_HIT	ARCR Access Hit Rate. This value will be added by the optimization/reordering mechanism to any pending access that has the same access type (read/write) as the previous access. Default value of is ARCR_ACC_HIT 0x0010 - encoding 2.
15–12 -	This field is reserved. Reserved
11–8 ARCR_DYN_JMP	ARCR Dynamic Jump. Each time an access wasn't chosen by the optimization/reordering mechanism then its dynamic score will be incremented by ARCR_DYN_JMP value. <b>NOTE:</b> Setting ARCR_DYN_JMP may cause starvation of low priority accesses <b>NOTE:</b> ARCR_DYN_JMP must be smaller than ARCR_DYN_MAX Default ARCR_DYN_JMP value is 0x0001 - encoding 1
7–4 ARCR_DYN_MAX	ARCR Dynamic Maximum. ARCR_DYN_MAX is the maximum dynamic score value that each access inside the optimization/reordering mechanism can get.  0000 0 0001 1 1111 15 (default)
3–0 ARCR_GUARD	ARCR Guard. After an access reached the maximum dynamic score value, it will wait additional ARCR_GUARD arbitration cycles and then will gain the highest priority in the optimization/reordering mechanism.  0000 15 (default) 0001 16 1111 30

### 32.12.17 MMDC Core Power Saving Control and Status Register (MMDC\_MAPSR)

The MAPSR determines the power saving features of MMDC. For further information see [Power Saving and Clock Frequency Change modes](#) .

Address: 21B\_0000h base + 404h offset = 21B\_0404h

**MMDC\_MAPSR field descriptions**

Field	Description
31–26 -	This field is reserved. Reserved
25 DVACK	General DVFS acknowledge. This read only bit indicates whether a dvfs acknowledge was asserted and that MMDC is in self-refresh mode
24 LPACK	General low-power acknowledge. This read only bit indicates whether a low-power acknowledge was asserted and that MMDC is in self-refresh mode
23–22 -	This field is reserved. Reserved
21 DVFS	General DVFS request. SW request for DVFS. Assertion of this bit will yield in self-refresh entry sequence 0 no dvfs request 1 dvfs request
20 LPMD	General LPMD request. SW request for LPMD. Assertion of this bit will yield in self-refresh entry sequence 0 no lpmd request 1 lpmd request
19–16 -	This field is reserved. Reserved
15–8 PST	Automatic Power saving timer. Valid only when PSD is set to "0". When the MMDC is idle for amount of cycles specified in that field then the DDR device will be entered automatically into self-refresh mode. The real value which is used is register-value multiplied by 64.  00000000 Reserved - this value is forbidden. 00000001 timer is configured to 64 clock cycles. 00000010 timer is configured to 128 clock cycles.

*Table continues on the next page...*

## MMDC\_MAPSR field descriptions (continued)

Field	Description
	00010000 (Default)- 1024 clock cycles. 11111111 timer clock is configured to 16320 clock cycles.
7 -	This field is reserved. Reserved.
6 WIS	Write Idle Status. This read only bit indicates whether write request buffer is idle (empty) or not. 0 idle 1 not idle
5 RIS	Read Idle Status. This read only bit indicates whether read request buffer is idle (empty) or not. 0 idle 1 not idle
4 PSS	Power Saving Status. This read only bit indicates whether the MMDC is in automatic power saving mode. 0 not in power saving 1 power saving
3-1 -	This field is reserved. Reserved.
0 PSD	Automatic Power Saving Disable. When the value of PSD is "0" (i.e automatic power saving is enabled) then the PST is activated and MMDC will enter automatically to self-refresh while the number of idle cycle reached.  <b>NOTE:</b> This bit must be disabled (i.e set to "1") during calibration process  0 power saving enabled 1 power saving disabled (default)

### 32.12.18 MMDC Core Exclusive ID Monitor Register0 (MMDC\_MAEXIDR0)

This register defines the ID to be monitored for exclusive accesses of monitor0 and monitor1. For further information see [Exclusive accesses handling](#).

Address: 21B\_0000h base + 408h offset = 21B\_0408h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**MMDC\_MAEXIDR0 field descriptions**

Field	Description
31–16 EXC_ID_MONITOR1	This feild defines ID for Exclusive monitor#1. Default value is 0x0020
15–0 EXC_ID_MONITOR0	This feild defines ID for Exclusive monitor#0. Default value is 0x0000

**32.12.19 MMDC Core Exclusive ID Monitor Register1 (MMDC\_MAEXIDR1)**

This register defines the ID to be monitored for exclusive accesses of monitor2 and monitor3. For further information see [Exclusive accesses handling](#) .

Address: 21B\_0000h base + 40Ch offset = 21B\_040Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	EXC_ID_MONITOR3																EXC_ID_MONITOR2															
W	EXC_ID_MONITOR3																EXC_ID_MONITOR2															
Reset	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

**MMDC\_MAEXIDR1 field descriptions**

Field	Description
31–16 EXC_ID_MONITOR3	This feild defines ID for Exclusive monitor#3. Default value is 0x0060
15–0 EXC_ID_MONITOR2	This feild defines ID for Exclusive monitor#2. Default value is 0x0040

## 32.12.20 MMDC Core Debug and Profiling Control Register 0 (MMDC\_MADPCR0)

Address: 21B\_0000h base + 410h offset = 21B\_0410h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								0				CYC_OVF	PRF_FRZ	DBG_RST	DBG_EN
W							SBS	SBS_EN					w1c			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**MMDC\_MADPCR0 field descriptions**

Field	Description
31–10 Reserved	This read-only field is reserved and always has the value 0.
9 SBS	Step By Step trigger. If SBS_EN is set to "1" then dispatching AXI pending access toward the DDR will done only if this bit is set to "1", otherwise no access will be dispatched toward the DDR. This bit is cleared when the pending access has been issued toward the DDR device.  1 Lanuch AXI pending access toward the DDR 0 No access will be launched toward the DDR
8 SBS_EN	Step By Step debug Enable. Enable step by step mode. Every time this mechanism is enabled then setting SBS to "1" will dispatch one pending AXI access to the DDR and in parallel its attributes will be observed in the status registes (MASBS0 and MASBS1). For further information see <a href="#">Step By Step (SBS) software monitor</a> .  0 disable 1 enable
7–4 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

**MMDC\_MADPCR0 field descriptions (continued)**

Field	Description
3 CYC_OVF	Total Profiling Cycles Count Overflow. When profiling mechanism is enabled (DBG_EN is set to "1") then this bit is asserted when overflow of CYC_COUNT occurred. Cleared by writing 1 to it.  0 no overflow 1 overflow
2 PRF_FRZ	Profiling freeze. When this bit is asserted then the profiling mechanism will be freezed and the associated status registers ( MADPSR0-MADPSR5) will hold the the current profiling values.  0 profiling counters are not frozen 1 profiling counters are frozen
1 DBG_RST	Debug and Profiling Reset. Reset all debug and profiling counters and components.  0 no reset 1 reset
0 DBG_EN	Debug and Profiling Enable. Enable debug and profiling mechanism. When this bit is asserted then the MMDC will perform a profiling based on the ID that is configured to MADPCR1. Upon assertion of PRF_FRZ the profiling will be freezed and the profiling results will be sampled to the status registers (MADPSR0-MADPSR5). For further information see <a href="#">MMDC Profiling</a> . default is "disable"  0 disable 1 enable

**32.12.21 MMDC Core Debug and Profiling Control Register 1 (MMDC\_MADPCR1)**

Address: 21B\_0000h base + 414h offset = 21B\_0414h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	PRF_AXI_ID_MASK																PRF_AXI_ID															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**MMDC\_MADPCR1 field descriptions**

Field	Description
31–16 PRF_AXI_ID_MASK	Profiling AXI ID Mask. AXI ID bits which masked by this value are chosen for profiling.  1 AXI ID specific bit is chosen for profiling 0 AXI ID specific bit is ignored (don't care)
15–0 PRF_AXI_ID	Profiling AXI ID. AXI IDs that matches a bit-wise AND logic operation between PRF_AXI_ID and PRF_AXI_ID_MASK are chosen for profiling.  Default value is 0x0, to choose any ID-s for profiling

32.12.22 MMDC Core Debug and Profiling Status Register 0 (MMDC\_MADPSR0)

Address: 21B\_0000h base + 418h offset = 21B\_0418h

MMDC\_MADPSR0 field descriptions

Field	Description
31–0 CYC_COUNT	Total Profiling cycle Count. This field reflects the total cycle count in case the profiling mechanism is enabled from assertion of DBG_EN and until PRF_FRZ is asserted

32.12.23 MMDC Core Debug and Profiling Status Register 1 (MMDC\_MADPSR1)

The register reflects the total cycles during which the MMDC state machines were busy (both writes and reads). This information can be used for DDR Utilization calculation.

Address: 21B\_0000h base + 41Ch offset = 21B\_041Ch

MMDC\_MADPSR1 field descriptions

Field	Description
31–0 BUSY_COUNT	Profiling Busy Cycles Count. This field reflects the total number of cycles where the MMDC read and write state machines were busy during the profiling period. Can be used for DDR utilization calculations

### 32.12.24 MMDC Core Debug and Profiling Status Register 2 (MMDC\_MADPSR2)

This register reflects the total number of read accesses (per AXI ID) toward MMDC.

Address: 21B\_0000h base + 420h offset = 21B\_0420h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RD_ACC_COUNT																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### MMDC\_MADPSR2 field descriptions

Field	Description
31–0 RD_ACC_COUNT	Profiling Read Access Count. This register reflects the total number of read accesses (per AXI ID) toward MMDC.

### 32.12.25 MMDC Core Debug and Profiling Status Register 3 (MMDC\_MADPSR3)

This register reflects the total number of write accesses (per AXI ID) toward MMDC.

Address: 21B\_0000h base + 424h offset = 21B\_0424h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WR_ACC_COUNT																															
W

#### MMDC\_MADPSR3 field descriptions

Field	Description
31–0 WR_ACC_COUNT	Profiling Write Access Count. This register reflects the total number of write accesses (per AXI ID) toward MMDC.

### 32.12.26 MMDC Core Debug and Profiling Status Register 4 (MMDC\_MADPSR4)

This register reflects the total number of bytes that were transferred during read access (per AXI ID) toward MMDC.

Address: 21B\_0000h base + 428h offset = 21B\_0428h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RD_BYTES_COUNT																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### MMDC\_MADPSR4 field descriptions

Field	Description
31–0 RD_BYTES_COUNT	Profiling Read Bytes Count. This register reflects the total number of bytes that were transferred during read access (per AXI ID) toward MMDC.

### 32.12.27 MMDC Core Debug and Profiling Status Register 5 (MMDC\_MADPSR5)

This register reflects the total number of bytes that were transferred during write access (per AXI ID) toward MMDC.

Address: 21B\_0000h base + 42Ch offset = 21B\_042Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WR_BYTES_COUNT																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### MMDC\_MADPSR5 field descriptions

Field	Description
31–0 WR_BYTES_COUNT	Profiling Write Bytes Count. This register reflects the total number of bytes that were transferred during write access (per AXI ID) toward MMDC.

## 32.12.28 MMDC Core Step By Step Address Register (MMDC\_MASBS0)

Address: 21B\_0000h base + 430h offset = 21B\_0430h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SBS_ADDR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**MMDC\_MASBS0 field descriptions**

Field	Description
31–0 SBS_ADDR	Step By Step Address. These bits reflect the address of the pending request in case of step by step mode.

## 32.12.29 MMDC Core Step By Step Address Attributes Register (MMDC\_MASBS1)

Address: 21B\_0000h base + 434h offset = 21B\_0434h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	SBS_AXI_ID															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SBS_LEN			SBS_BUFF	SBS_BURST		SBS_SIZE			SBS_PROT			SBS_LOCK		SBS_TYPE	SBS_VLD
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**MMDC\_MASBS1 field descriptions**

Field	Description
31–16 SBS_AXI_ID	Step By Step AXI ID. These bits reflect the AXI ID of the pending request in case of step by step mode.
15–13 SBS_LEN	Step By Step Length. These bits reflect the AXI LENGTH of the pending request in case of step by step mode.  000 burst of length 1 001 burst of length 2 111 burst of length 8
12 SBS_BUFF	Step By Step Buffered. This bit reflect the AXI CACHE[0] of the pending request in case of step by step mode. Relevant only for write requests

*Table continues on the next page...*

### MMDC\_MASBS1 field descriptions (continued)

Field	Description
11–10 SBS_BURST	Step By Step Burst. These bits reflect the AXI BURST of the pending request in case of step by step mode.  00 FIXED 01 INCR burst 10 WRAP burst 11 reserved
9–7 SBS_SIZE	Step By Step Size. These bits reflect the AXI SIZE of the pending request in case of step by step mode.  000 8 bits 001 16 bits 010 32 bits 011 64 bits 100 128bits 101-111 Reserved
6–4 SBS_PROT	Step By Step Protection. These bits reflect the AXI PROT of the pending request in case of step by step mode.
3–2 SBS_LOCK	Step By Step Lock. These bits reflect the AXI LOCK of the pending request in case of step by step mode.
1 SBS_TYPE	Step By Step Request Type. These bits reflect the type (read/write) of the pending request in case of step by step mode.  0 write 1 read
0 SBS_VLD	Step By Step Valid. This bit reflects whether there is a pending request in case of step by step mode.  0 not valid 1 valid

## 32.12.30 MMDC Core General Purpose Register (MMDC\_MAGENP)

This register is a general 32 bit read/write register.

Address: 21B\_0000h base + 440h offset = 21B\_0440h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### MMDC\_MAGENP field descriptions

Field	Description
31–0 GP31_GP0	General purpose read/write bits.

### 32.12.31 MMDC PHY ZQ HW control register (MMDC\_MPZQHWCTRL)

Address: 21B\_0000h base + 800h offset = 21B\_0800h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ZQ_EARLY_COMPARATOR_EN_TIMER					0	TZQ_CS			TZQ_OPER			TZQ_INIT			ZQ_HW_FOR
W																
Reset	1	0	1	0	0	0	0	1	0	0	1	1	1	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ZQ_HW_PD_RES					ZQ_HW_PU_RES					ZQ_HW_PER					ZQ_MODE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### MMDC\_MPZQHWCTRL field descriptions

Field	Description
31–27 ZQ_EARLY_COMPARATOR_EN_TIMER	ZQ early comparator enable timer. This timer defines the interval between the warming up of the comparator of the i.MX ZQ calibration pad and the beginning of the ZQ calibration process with the pad 0x0 - 0x6 Reserved 0x7 8 cycles 0x14 21 cycles (Default) 0x1E 31 cycles 0x1F 32 cycles
26 Reserved	This read-only field is reserved and always has the value 0.
25–23 TZQ_CS	Device ZQ short time. This field holds the number of cycles that are required by the external DDR device to perform ZQ short calibration. Upon driving the command to the DDR device then no further accesses will be issued to the DDR device till satisfying that time. <b>NOTE:</b> In LPDDR2 the ZQ short time is taken from MPZQLP2CTL[ZQ_LP2_HW_ZQCS] <b>NOTE:</b> This field should not be update during ZQ calibration. 000 Reserved 001 Reserved 010 128 cycles (Default) 011 256 cycles 100 512 cycles 101 1024 cycles 110- 111 Resreved
22–20 TZQ_OPER	Device ZQ long/oper time. This field holds the number of cycles that are required by the external DDR device to perform ZQ long calibration except the first ZQ long command that is issued after reset. Upon driving the command to the DDR device then no further accesses will be issued to the DDR device till satisfying that time. <b>NOTE:</b> In LPDDR2 the ZQ oper time is taken from MPZQLP2CTL[ZQ_LP2_HW_ZQCL]

Table continues on the next page...

### MMDC\_MPZQHWCTRL field descriptions (continued)

Field	Description
	<p><b>NOTE:</b> This field should not be update during ZQ calibration.</p> <p>000 Reserved</p> <p>001 Reserved</p> <p>010 128 cycles</p> <p>011 256 cycles - Default (JEDEC value for DDR3)</p> <p>100 512 cycles</p> <p>101 1024 cycles</p> <p>110- 111 Resreved</p>
19–17 TZQ_INIT	<p>Device ZQ long/init time. This field holds the number of cycles that are required by the external DDR device to perform ZQ long calibration right after reset. Upon driving the command to the DDR device then no further accesses will be issued to the DDR device till satisfying that time.</p> <p><b>NOTE:</b> In LPDDR2 the ZQ init time is taken from MPZQLP2CTL[ZQ_LP2_HW_ZQINIT]</p> <p><b>NOTE:</b> This field should not be update during ZQ calibration.</p> <p>000 Reserved</p> <p>001 Reserved</p> <p>010 128 cycles</p> <p>011 256 cycles</p> <p>100 512 cycles - Default (JEDEC value for DDR3)</p> <p>101 1024 cycles</p> <p>110- 111 Resreved</p>
16 ZQ_HW_FOR	<p>Force ZQ automatic calibration process with the i.MX ZQ calibration pad. When this bit is asserted then the MMDC will issue one ZQ automatic calibration process with the i.MX ZQ calibration pad. It is the user responsibility to make sure that all the accesses to DDR will be finished before asserting this bit using CON_REQ/CON_ACK mechanism. HW will negate this bit upon completion of the ZQ calibration process. Upon negation of this bit the ZQ HW calibration pull-up and pull-down results (ZQ_HW_PU_RES and ZQ_HW_PD_RES respectively) are valid</p> <p><b>NOTE:</b> In order to enable this bit ZQ_MODE must be set to either "1" or "3"</p>
15–11 ZQ_HW_PD_RES	<p>ZQ HW calibration pull-down result. This field holds the pull-down resistor value calculated at the end of the ZQ automatic calibration process with the i.MX ZQ calibration pad.</p> <p>00000 Max. resistance.</p> <p>11111 Min. resistance.</p>
10–6 ZQ_HW_PU_RES	<p>ZQ automatic calibration pull-up result. This field holds the pull-up resistor value calculated at the end of the ZQ automatic calibration process with the i.MX ZQ calibration pad.</p> <p>00000 Min. resistance.</p> <p>11111 Max. resistance.</p>
5–2 ZQ_HW_PER	<p>ZQ periodic calibration time. This field determines how often the periodic ZQ calibration is performed.</p> <p>This field is applied for both ZQ short calibration and ZQ automatic calibration process with i.MX ZQ calibration pad. Whenever this timer is expired then according to ZQ_MODE the ZQ automatic calibration process with the i.MX ZQ calibration pad will be issued and/or short/long command will be issued to the external DDR device.</p> <p>This field is ignored if ZQ_MODE equals "00"</p> <p>0000 ZQ calibration is performed every 1 ms.</p> <p>0001 ZQ calibration is performed every 2 ms.</p>

*Table continues on the next page...*

**MMDC\_MPZQHWCTRL field descriptions (continued)**

Field	Description
	0010 ZQ calibration is performed every 4 ms. 1010 ZQ calibration is performed every 1 ms. 1110 ZQ calibration is performed every 16 ms. 1111 ZQ calibration is performed every 32 ms.
1–0 ZQ_MODE	ZQ calibration mode: 0x0 No ZQ calibration is issued. (Default) 0x1 ZQ calibration is issued to i.MX ZQ calibration pad together with ZQ long command to the external DDR device only when exiting self refresh. 0x2 ZQ calibration command long/short is issued only to the external DDR device periodically and when exiting self refresh 0x3 ZQ calibration is issued to i.MX ZQ calibration pad together with ZQ calibration command long/short to the external DDR device periodically and when exiting self refresh

### 32.12.32 MMDC PHY ZQ SW control register (MMDC\_MPZQSWCTRL)

Address: 21B\_0000h base + 804h offset = 21B\_0804h

MMDC\_MPZQSWCTRL field descriptions

Field	Description
31–18 Reserved	This read-only field is reserved and always has the value 0.
17–16 ZQ_CMP_OUT_SMP	Defines the amount of cycles between driving the ZQ signals to the ZQ pad and till sampling the comparator enable output while performing ZQ calibration process with the i.MX ZQ calibration pad  00 7 cycles 01 15 cycles

Table continues on the next page...

**MMDC\_MPZQSWCTRL field descriptions (continued)**

Field	Description
	10 23 cycles 11 31 cycles
15–14 Reserved	This read-only field is reserved and always has the value 0.
13 USE_ZQ_SW_VAL	Use SW ZQ configured value for I/O pads resistor controls. This bit selects whether ZQ SW value or ZQ HW value will be driven to the I/O pads resistor controls. By default this bit is cleared and MMDC drives the HW ZQ status bits on the resistor controls of the I/O pads.  <b>NOTE:</b> This bit should not be updated during ZQ calibration.  0 Fields ZQ_HW_PD_VAL & ZQ_HW_PU_VAL will be driven to I/O pads resistor controls. 1 Fields ZQ_SW_PD_VAL & ZQ_SW_PU_VAL will be driven to I/O pads resistor controls.
12 ZQ_SW_PD	ZQ software PU/PD calibration. This bit determines the calibration stage (PU or PD).  0 PU resistor calibration 1 PD resistor calibration
11–7 ZQ_SW_PD_VAL	ZQ software pull-down resistance. This field determines the value of the PD resistor during SW ZQ calibration.  00000 Max. resistance. 11111 Min. resistance.
6–2 ZQ_SW_PU_VAL	ZQ software pull-up resistance. This field determines the value of the PU resistor during SW ZQ calibration.  00000 Min. resistance. 11111 Max. resistance.
1 ZQ_SW_RES	ZQ software calibration result. This bit reflects the ZQ calibration voltage comparator value.  0 Current ZQ calibration voltage is less than VDD/2. 1 Current ZQ calibration voltage is more than VDD/2
0 ZQ_SW_FOR	ZQ SW calibration enable. This bit when asserted enables ZQ SW calibration. HW negates this bit upon completion of the ZQ SW calibration. Upon negation of this bit the ZQ SW calibration result (i.e ZQ_SW_RES) is valid

### 32.12.33 MMDC PHY Write Leveling Configuration and Error Status Register (MMDC\_MPWLGCR)

Address: 21B\_0000h base + 808h offset = 21B\_0808h

MMDC\_MPWLGCR field descriptions

Field	Description
31–12 -	This field is reserved. Reserved
11 WL_HW_ERR3	Byte3 write-leveling HW calibration error. This bit is asserted when an error was found on byte3 during write-leveling HW calibration.  This bit is valid only upon completion of the write-leveling HW calibration (i.e HW_WL_EN bit is de-asserted)  0 No error was found on byte3 during write-leveling HW calibration. 1 An error was found on byte3 during write-leveling HW calibration.
10 WL_HW_ERR2	Byte2 write-leveling HW calibration error. This bit is asserted when an error was found on byte2 during write-leveling HW calibration.  This bit is valid only upon completion of the write-leveling HW calibration (i.e HW_WL_EN bit is de-asserted)  0 No error was found on byte2 during write-leveling HW calibration. 1 An error was found on byte2 during write-leveling HW calibration.
9 WL_HW_ERR1	Byte1 write-leveling HW calibration error. This bit is asserted when an error was found on byte1 during write-leveling HW calibration.

Table continues on the next page...

### MMDC\_MPWLGCRC field descriptions (continued)

Field	Description
	<p>This bit is valid only upon completion of the write-leveling HW calibration (i.e HW_WL_EN bit is de-asserted)</p> <p>0 No error was found on byte1 during write-leveling HW calibration.</p> <p>1 An error was found on byte1 during write-leveling HW calibration.</p>
8 WL_HW_ERR0	<p>Byte0 write-leveling HW calibration error. This bit is asserted when an error was found on byte0 during write-leveling HW calibration.</p> <p>This bit is valid only upon completion of the write-leveling HW calibration (i.e HW_WL_EN bit is de-asserted)</p> <p>0 No error was found on byte0 during write-leveling HW calibration.</p> <p>1 An error was found on byte0 during write-leveling HW calibration.</p>
7 WL_SW_RES3	<p>Byte3 write-leveling software result. This bit reflects the value that is driven by the DDR device on DQ24 during SW write-leveling.</p> <p>0 DQS3 sampled low CK during SW write-leveling.</p> <p>1 DQS3 sampled high CK during SW write-leveling.</p>
6 WL_SW_RES2	<p>Byte2 write-leveling software result. This bit reflects the value that is driven by the DDR device on DQ16 during SW write-leveling.</p> <p>0 DQS2 sampled low CK during SW write-leveling.</p> <p>1 DQS2 sampled high CK during SW write-leveling.</p>
5 WL_SW_RES1	<p>Byte1 write-leveling software result. This bit reflects the value that is driven by the DDR device on DQ8 during SW write-leveling.</p> <p>0 DQS1 sampled low CK during SW write-leveling.</p> <p>1 DQS1 sampled high CK during SW write-leveling.</p>
4 WL_SW_RES0	<p>Byte0 write-leveling software result. This bit reflects the value that is driven by the DDR device on DQ0 during SW write-leveling.</p> <p>0 DQS0 sampled low CK during SW write-leveling.</p> <p>1 DQS0 sampled high CK during SW write-leveling.</p>
3 -	<p>This field is reserved.</p> <p>Reserved</p>
2 SW_WL_CNT_EN	<p>SW write-leveling count down enable. This bit when asserted set a certain delay of (25+15) cycles from the setting of SW_WL_EN and before driving the DQS to the DDR device. This bit should be asserted before the first SW write-leveling request and after issuing the write leveling MRS command</p> <p>0 MMDC doesn't count 25+15 cycles before issuing write-leveling DQS.</p> <p>1 MMDC counts 25+15 cycles before issuing write-leveling DQS.</p>
1 SW_WL_EN	<p>Write-Leveling SW enable. If this bit is asserted then the MMDC will perform one write-leveling iteration with the DDR device (assuming that Write-Leveling procedure is already enabled in the DDR device through MRS command). HW negate this bit upon completion of the SW write-leveling. Negation of this bit also points that the write-leveling SW calibration result is valid</p> <p><b>NOTE:</b> If this bit and the SW_WL_CNT_EN are enabled the MMDC counts 25 + 15 cycles before issuing the SW write-leveling DQS.</p>
0 HW_WL_EN	<p>Write-Leveling HW (automatic) enable. If this bit is asserted then the MMDC will perform the whole Write-Leveling sequence with the DDR device (assuming that Write-Leveling procedure is already enabled in the DDR device through MRS command). HW negates this bit upon completion of the HW write-leveling. Negation of this bit also points that the write-leveling HW calibration results are valid</p>

*Table continues on the next page...*

**MMDC\_MPWLGCR field descriptions (continued)**

Field	Description
	<b>NOTE:</b> Before issuing the first DQS the MMDC counts 25 + 15 cycles automatically as required by the standard.

#### MMDC\_MPRDDQBY1DL field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–28 rd_dq15_del	Read dqs1 to dq15 delay fine-tuning. This field holds the number of delay units that are added to dq15 relative to dqs1.  000 No change in dq15 delay 001 Add dq15 delay of 1 delay unit 010 Add dq15 delay of 2 delay units. 011 Add dq15 delay of 3 delay units. 100 Add dq15 delay of 4 delay units. 101 Add dq15 delay of 5 delay units. 110 Add dq15 delay of 6 delay units. 111 Add dq15 delay of 7 delay units.
27 Reserved	This read-only field is reserved and always has the value 0.
26–24 rd_dq14_del	Read dqs1 to dq14 delay fine-tuning. This field holds the number of delay units that are added to dq14 relative to dqs1.  000 No change in dq14 delay 001 Add dq14 delay of 1 delay unit 010 Add dq14 delay of 2 delay units. 011 Add dq14 delay of 3 delay units. 100 Add dq14 delay of 4 delay units. 101 Add dq14 delay of 5 delay units. 110 Add dq14 delay of 6 delay units. 111 Add dq14 delay of 7 delay units.

Table continues on the next page...

### MMDC\_MPRDDQBY1DL field descriptions (continued)

Field	Description
23 Reserved	This read-only field is reserved and always has the value 0.
22–20 rd_dq13_del	Read dqs1 to dq13 delay fine-tuning. This field holds the number of delay units that are added to dq13 relative to dqs1.  000 No change in dq13 delay 001 Add dq13 delay of 1 delay unit 010 Add dq13 delay of 2 delay units. 011 Add dq13 delay of 3 delay units. 100 Add dq13 delay of 4 delay units. 101 Add dq13 delay of 5 delay units. 110 Add dq13 delay of 6 delay units. 111 Add dq13 delay of 7 delay units.
19 Reserved	This read-only field is reserved and always has the value 0.
18–16 rd_dq12_del	Read dqs1 to dq12 delay fine-tuning. This field holds the number of delay units that are added to dq12 relative to dqs1.  000 No change in dq12 delay 001 Add dq12 delay of 1 delay unit 010 Add dq12 delay of 2 delay units. 011 Add dq12 delay of 3 delay units. 100 Add dq12 delay of 4 delay units. 101 Add dq12 delay of 5 delay units. 110 Add dq12 delay of 6 delay units. 111 Add dq12 delay of 7 delay units.
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 rd_dq11_del	Read dqs1 to dq11 delay fine-tuning. This field holds the number of delay units that are added to dq11 relative to dqs1.  000 No change in dq11 delay 001 Add dq11 delay of 1 delay unit 010 Add dq11 delay of 2 delay units. 011 Add dq11 delay of 3 delay units. 100 Add dq11 delay of 4 delay units. 101 Add dq11 delay of 5 delay units. 110 Add dq11 delay of 6 delay units. 111 Add dq11 delay of 7 delay units.
11 Reserved	This read-only field is reserved and always has the value 0.
10–8 rd_dq10_del	Read dqs1 to dq10 delay fine-tuning. This field holds the number of delay units that are added to dq10 relative to dqs1.  000 No change in dq10 delay 001 Add dq10 delay of 1 delay unit 010 Add dq10 delay of 2 delay units. 011 Add dq10 delay of 3 delay units.

Table continues on the next page...

**MMDC\_MPRDDQBY1DL field descriptions (continued)**

Field	Description
	100 Add dq10 delay of 4 delay units. 101 Add dq10 delay of 5 delay unit 110 Add dq10 delay of 6 delay units. 111 Add dq10 delay of 7 delay units.
7 Reserved	This read-only field is reserved and always has the value 0.
6–4 rd_dq9_del	Read dqs1 to dq9 delay fine-tuning. This field holds the number of delay units that are added to dq9 relative to dqs1.  000 No change in dq9 delay 001 Add dq9 delay of 1 delay unit 010 Add dq9 delay of 2 delay units. 011 Add dq9 delay of 3 delay units. 100 Add dq9 delay of 4 delay units. 101 Add dq9 delay of 5 delay units. 110 Add dq9 delay of 6 delay units. 111 Add dq9 delay of 7 delay units.
3 Reserved	This read-only field is reserved and always has the value 0.
2–0 rd_dq8_del	Read dqs1 to dq8 delay fine-tuning. This field holds the number of delay units that are added to dq8 relative to dqs1.  000 No change in dq8 delay 001 Add dq8 delay of 1 delay unit 010 Add dq8 delay of 2 delay units. 011 Add dq8 delay of 3 delay units. 100 Add dq8 delay of 4 delay units. 101 Add dq8 delay of 5 delay units. 110 Add dq8 delay of 6 delay units. 111 Add dq8 delay of 7 delay units.

## 32.12.40 MMDC PHY Read DQ Byte2 Delay Register (MMDC\_MPRDDQBY2DL)

This register is used to add fine-tuning adjustment to every bit in the read DQ byte2 relative to the read DQS

Address: 21B\_0000h base + 824h offset = 21B\_0824h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### MMDC\_MPRDDQBY2DL field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–28 rd_dq23_del	Read dqs2 to dq23 delay fine-tuning. This field holds the number of delay units that are added to dq23 relative to dqs2.  000 No change in dq23 delay 001 Add dq23 delay of 1 delay unit 010 Add dq23 delay of 2 delay units. 011 Add dq23 delay of 3 delay units. 100 Add dq23 delay of 4 delay units. 101 Add dq23 delay of 5 delay units. 110 Add dq23 delay of 6 delay units. 111 Add dq23 delay of 7 delay units.
27 Reserved	This read-only field is reserved and always has the value 0.
26–24 rd_dq22_del	Read dqs2 to dq22 delay fine-tuning. This field holds the number of delay units that are added to dq22 relative to dqs2.  000 No change in dq22 delay 001 Add dq22 delay of 1 delay unit 010 Add dq22 delay of 2 delay units. 011 Add dq22 delay of 3 delay units. 100 Add dq22 delay of 4 delay units. 101 Add dq22 delay of 5 delay units. 110 Add dq22 delay of 6 delay units. 111 Add dq22 delay of 7 delay units.

Table continues on the next page...

**MMDC\_MPRDDQBY2DL field descriptions (continued)**

Field	Description
23 Reserved	This read-only field is reserved and always has the value 0.
22–20 rd_dq21_del	Read dqs2 to dq21 delay fine-tuning. This field holds the number of delay units that are added to dq21 relative to dqs2.  000 No change in dq21 delay 001 Add dq21 delay of 1 delay unit 010 Add dq21 delay of 2 delay units. 011 Add dq21 delay of 3 delay units. 100 Add dq21 delay of 4 delay units. 101 Add dq21 delay of 5 delay units. 110 Add dq21 delay of 6 delay units. 111 Add dq21 delay of 7 delay units.
19 Reserved	This read-only field is reserved and always has the value 0.
18–16 rd_dq20_del	Read dqs2 to dq20 delay fine-tuning. This field holds the number of delay units that are added to dq20 relative to dqs2.  000 No change in dq20 delay 001 Add dq20 delay of 1 delay unit 010 Add dq20 delay of 2 delay units. 011 Add dq20 delay of 3 delay units. 100 Add dq20 delay of 4 delay units. 101 Add dq20 delay of 5 delay units. 110 Add dq20 delay of 6 delay units. 111 Add dq20 delay of 7 delay units.
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 rd_dq19_del	Read dqs2 to dq19 delay fine-tuning. This field holds the number of delay units that are added to dq19 relative to dqs2.  000 No change in dq19 delay 001 Add dq19 delay of 1 delay unit 010 Add dq19 delay of 2 delay units. 011 Add dq19 delay of 3 delay units. 100 Add dq19 delay of 4 delay units. 101 Add dq19 delay of 5 delay units. 110 Add dq19 delay of 6 delay units. 111 Add dq19 delay of 7 delay units.
11 Reserved	This read-only field is reserved and always has the value 0.
10–8 rd_dq18_del	Read dqs2 to dq18 delay fine-tuning. This field holds the number of delay units that are added to dq18 relative to dqs2.  000 No change in dq18 delay 001 Add dq18 delay of 1 delay unit 010 Add dq18 delay of 2 delay units. 011 Add dq18 delay of 3 delay units.

*Table continues on the next page...*

### MMDC\_MPRDDQBY2DL field descriptions (continued)

Field	Description
	100 Add dq18 delay of 4 delay units. 101 Add dq18 delay of 5 delay units. 110 Add dq18 delay of 6 delay units. 111 Add dq18 delay of 7 delay units.
7 Reserved	This read-only field is reserved and always has the value 0.
6–4 rd_dq17_del	Read dqs2 to dq17 delay fine-tuning. This field holds the number of delay units that are added to dq17 relative to dqs2.  000 No change in dq17 delay 001 Add dq17 delay of 1 delay unit 010 Add dq17 delay of 2 delay units. 011 Add dq17 delay of 3 delay units. 100 Add dq17 delay of 4 delay units. 101 Add dq17 delay of 5 delay units. 110 Add dq17 delay of 6 delay units. 111 Add dq17 delay of 7 delay units.
3 Reserved	This read-only field is reserved and always has the value 0.
2–0 rd_dq16_del	Read dqs2 to dq16 delay fine-tuning. This field holds the number of delay units that are added to dq16 relative to dqs2.  000 No change in dq16 delay 001 Add dq16 delay of 1 delay unit 010 Add dq16 delay of 2 delay units. 011 Add dq16 delay of 3 delay units. 100 Add dq16 delay of 4 delay units. 101 Add dq16 delay of 5 delay units. 110 Add dq16 delay of 6 delay units. 111 Add dq16 delay of 7 delay units.

### 32.12.41 MMDC PHY Read DQ Byte3 Delay Register (MMDC\_MPRDDQBY3DL)

This register is used to add fine-tuning adjustment to every bit in the read DQ byte3 relative to the read DQS.

The bit assignments and the bit field descriptions for the register are shown below.

Address: 21B\_0000h base + 828h offset = 21B\_0828h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**MMDC\_MPRDDQBY3DL field descriptions**

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–28 rd_dq31_del	Read dqs3 to dq31 delay fine-tuning. This field holds the number of delay units that are added to dq31 relative to dqs3.  000 No change in dq31 delay 001 Add dq31 delay of 1 delay unit 010 Add dq31 delay of 2 delay units. 011 Add dq31 delay of 3 delay units. 100 Add dq31 delay of 4 delay units. 101 Add dq31 delay of 5 delay units. 110 Add dq31 delay of 6 delay units. 111 Add dq31 delay of 7 delay units.
27 Reserved	This read-only field is reserved and always has the value 0.
26–24 rd_dq30_del	Read dqs3 to dq30 delay fine-tuning. This field holds the number of delay units that are added to dq30 relative to dqs3.  000 No change in dq30 delay 001 Add dq30 delay of 1 delay unit 010 Add dq30 delay of 2 delay units. 011 Add dq30 delay of 3 delay units. 100 Add dq30 delay of 4 delay units. 101 Add dq30 delay of 5 delay units. 110 Add dq30 delay of 6 delay units. 111 Add dq30 delay of 7 delay units.
23 Reserved	This read-only field is reserved and always has the value 0.
22–20 rd_dq29_del	Read dqs3 to dq29 delay fine-tuning. This field holds the number of delay units that are added to dq29 relative to dqs3.  000 No change in dq29 delay 001 Add dq29 delay of 1 delay unit 010 Add dq29 delay of 2 delay units. 011 Add dq29 delay of 3 delay units. 100 Add dq29 delay of 4 delay units. 101 Add dq29 delay of 5 delay units. 110 Add dq29 delay of 6 delay units. 111 Add dq29 delay of 7 delay units.
19 Reserved	This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

### MMDC\_MPRDDQBY3DL field descriptions (continued)

Field	Description
18–16 rd_dq28_del	Read dqs3 to dq28 delay fine-tuning. This field holds the number of delay units that are added to dq28 relative to dqs3.  000 No change in dq28 delay 001 Add dq28 delay of 1 delay unit 010 Add dq28 delay of 2 delay units. 011 Add dq28 delay of 3 delay units. 100 Add dq28 delay of 4 delay units. 101 Add dq28 delay of 5 delay units. 110 Add dq28 delay of 6 delay units. 111 Add dq28 delay of 7 delay units.
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 rd_dq27_del	Read dqs3 to dq27 delay fine-tuning. This field holds the number of delay units that are added to dq27 relative to dqs3.  000 No change in dq27 delay 001 Add dq27 delay of 1 delay unit 010 Add dq27 delay of 2 delay units. 011 Add dq27 delay of 3 delay units. 100 Add dq27 delay of 4 delay units. 101 Add dq27 delay of 5 delay units. 110 Add dq27 delay of 6 delay units. 111 Add dq27 delay of 7 delay units.
11 Reserved	This read-only field is reserved and always has the value 0.
10–8 rd_dq26_del	Read dqs3 to dq26 delay fine-tuning. This field holds the number of delay units that are added to dq26 relative to dqs3.  000 No change in dq26 delay 001 Add dq26 delay of 1 delay unit 010 Add dq26 delay of 2 delay units. 011 Add dq26 delay of 3 delay units. 100 Add dq26 delay of 4 delay units. 101 Add dq26 delay of 5 delay units. 110 Add dq26 delay of 6 delay units. 111 Add dq26 delay of 7 delay units.
7 Reserved	This read-only field is reserved and always has the value 0.
6–4 rd_dq25_del	Read dqs3 to dq25 delay fine-tuning. This field holds the number of delay units that are added to dq25 relative to dqs3.  000 No change in dq25 delay 001 Add dq25 delay of 1 delay unit 010 Add dq25 delay of 2 delay units. 011 Add dq25 delay of 3 delay units. 100 Add dq25 delay of 4 delay units. 101 Add dq25 delay of 5 delay units.

Table continues on the next page...

**MMDC\_MPRDDQBY3DL field descriptions (continued)**

Field	Description
	110 Add dq25 delay of 6 delay units. 111 Add dq25 delay of 7 delay units.
3 Reserved	This read-only field is reserved and always has the value 0.
2–0 rd_dq24_del	Read dqs3 to dq24 delay fine-tuning. This field holds the number of delay units that are added to dq24 relative to dqs3.  000 No change in dq24 delay 001 Add dq24 delay of 1 delay unit 010 Add dq24 delay of 2 delay units. 011 Add dq24 delay of 3 delay units. 100 Add dq24 delay of 4 delay units. 101 Add dq24 delay of 5 delay units. 110 Add dq24 delay of 6 delay units. 111 Add dq24 delay of 7 delay units.

**32.12.42 MMDC PHY Write DQ Byte0 Delay Register (MMDC\_MPWRDQBY0DL)**

This register is used to add fine-tuning adjustment to every bit in the write DQ byte0 relative to the write DQS

Address: 21B\_0000h base + 82Ch offset = 21B\_082Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**MMDC\_MPWRDQBY0DL field descriptions**

Field	Description
31–30 wr_dm0_del	Write dm0 delay fine-tuning. This field holds the number of delay units that are added to dm0 relative to dqs0.  00 No change in dm0 delay 01 Add dm0 delay of 1 delay unit. 10 Add dm0 delay of 2 delay units. 11 Add dm0 delay of 3 delay units.

*Table continues on the next page...*

### MMDC\_MPWRDQBY0DL field descriptions (continued)

Field	Description
29–28 wr_dq7_del	Write dq7 delay fine-tuning. This field holds the number of delay units that are added to dq7 relative to dqs0.  00 No change in dq7 delay 01 Add dq7 delay of 1 delay unit. 10 Add dq7 delay of 2 delay units. 11 Add dq7 delay of 3 delay units.
27–26 Reserved	This read-only field is reserved and always has the value 0.
25–24 wr_dq6_del	Write dq6 delay fine-tuning. This field holds the number of delay units that are added to dq6 relative to dqs0.  00 No change in dq6 delay 01 Add dq6 delay of 1 delay unit. 10 Add dq6 delay of 2 delay units. 11 Add dq6 delay of 3 delay units.
23–22 Reserved	This read-only field is reserved and always has the value 0.
21–20 wr_dq5_del	Write dq5 delay fine-tuning. This field holds the number of delay units that are added to dq5 relative to dqs0.  00 No change in dq5 delay 01 Add dq5 delay of 1 delay unit. 10 Add dq5 delay of 2 delay units. 11 Add dq5 delay of 3 delay units.
19–18 Reserved	This read-only field is reserved and always has the value 0.
17–16 wr_dq4_del	Write dq4 delay fine-tuning. This field holds the number of delay units that are added to dq4 relative to dqs0.  00 No change in dq4 delay 01 Add dq4 delay of 1 delay unit.. 10 Add dq4 delay of 2 delay units. 11 Add dq4 delay of 3 delay units.
15–14 Reserved	This read-only field is reserved and always has the value 0.
13–12 wr_dq3_del	Write dq3 delay fine-tuning. This field holds the number of delay units that are added to dq3 relative to dqs0.  00 No change in dq3 delay 01 Add dq3 delay of 1 delay unit. 10 Add dq3 delay of 2 delay units. 11 Add dq3 delay of 3 delay units.
11–10 Reserved	This read-only field is reserved and always has the value 0.
9–8 wr_dq2_del	Write dq2 delay fine-tuning. This field holds the number of delay units that are added to dq2 relative to dqs0.  00 No change in dq2 delay

Table continues on the next page...

**MMDC\_MPWRDQBY0DL field descriptions (continued)**

Field	Description
	01 Add dq2 delay of 1 delay unit. 10 Add dq2 delay of 2 delay units. 11 Add dq2 delay of 3 delay units.
7–6 Reserved	This read-only field is reserved and always has the value 0.
5–4 wr_dq1_del	Write dq1 delay fine-tuning. This field holds the number of delay units that are added to dq1 relative to dqs0.  00 No change in dq1 delay 01 Add dq1 delay of 1 delay unit. 10 Add dq1 delay of 2 delay units. 11 Add dq1 delay of 3 delay units.
3–2 Reserved	This read-only field is reserved and always has the value 0.
1–0 wr_dq0_del	Write dq0 delay fine-tuning. This field holds the number of delay units that are added to dq0 relative to dqs0.  00 No change in dq0 delay 01 Add dq0 delay of 1 delay unit. 10 Add dq0 delay of 2 delay units. 11 Add dq0 delay of 3 delay units.

**32.12.43 MMDC PHY Write DQ Byte1 Delay Register (MMDC\_MPWRDQBY1DL)**

This register is used to add fine-tuning adjustment to every bit in the write DQ byte1 relative to the write DQS

Address: 21B\_0000h base + 830h offset = 21B\_0830h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**MMDC\_MPWRDQBY1DL field descriptions**

Field	Description
31–30 wr_dm1_del	Write dm1 delay fine-tuning. This field holds the number of delay units that are added to dm1 relative to dqs1.

Table continues on the next page...

### MMDC\_MPWRDQBY1DL field descriptions (continued)

Field	Description
	00 No change in dm1 delay 01 Add dm1 delay of 1 delay unit. 10 Add dm1 delay of 2 delay units. 11 Add dm1 delay of 3 delay units.
29–28 wr_dq15_del	Write dq15 delay fine-tuning. This field holds the number of delay units that are added to dq15 relative to dqs1.  00 No change in dq15 delay 01 Add dq15 delay of 1 delay unit. 10 Add dq15 delay of 2 delay units. 11 Add dq15 delay of 3 delay units.
27–26 Reserved	This read-only field is reserved and always has the value 0.
25–24 wr_dq14_del	Write dq14 delay fine-tuning. This field holds the number of delay units that are added to dq14 relative to dqs1.  00 No change in dq14 delay 01 Add dq14 delay of 1 delay unit. 10 Add dq14 delay of 2 delay units. 11 Add dq14 delay of 3 delay units.
23–22 Reserved	This read-only field is reserved and always has the value 0.
21–20 wr_dq13_del	Write dq13 delay fine-tuning. This field holds the number of delay units that are added to dq13 relative to dqs1.  00 No change in dq13 delay 01 Add dq13 delay of 1 delay unit. 10 Add dq13 delay of 2 delay units. 11 Add dq13 delay of 3 delay units.
19–18 Reserved	This read-only field is reserved and always has the value 0.
17–16 wr_dq12_del	Write dq12 delay fine-tuning. This field holds the number of delay units that are added to dq12 relative to dqs1.  00 No change in dq12 delay 01 Add dq12 delay of 1 delay unit. 10 Add dq12 delay of 2 delay units. 11 Add dq12 delay of 3 delay units.
15–14 Reserved	This read-only field is reserved and always has the value 0.
13–12 wr_dq11_del	Write dq11 delay fine-tuning. This field holds the number of delay units that are added to dq11 relative to dqs1.  00 No change in dq11 delay 01 Add dq11 delay of 1 delay unit. 10 Add dq11 delay of 2 delay units. 11 Add dq11 delay of 3 delay units.

Table continues on the next page...

**MMDC\_MPWRDQBY1DL field descriptions (continued)**

Field	Description
11–10 Reserved	This read-only field is reserved and always has the value 0.
9–8 wr_dq10_del	Write dq10 delay fine-tuning. This field holds the number of delay units that are added to dq10 relative to dqs1.  00 No change in dq10 delay 01 Add dq10 delay of 1 delay unit. 10 Add dq10 delay of 2 delay units. 11 Add dq10 delay of 3 delay units.
7–6 Reserved	This read-only field is reserved and always has the value 0.
5–4 wr_dq9_del	Write dq9 delay fine-tuning. This field holds the number of delay units that are added to dq9 relative to dqs1.  00 No change in dq9 delay 01 Add dq9 delay of 1 delay unit. 10 Add dq9 delay of 2 delay units. 11 Add dq9 delay of 3 delay units.
3–2 Reserved	This read-only field is reserved and always has the value 0.
1–0 wr_dq8_del	Write dq8 delay fine-tuning. This field holds the number of delay units that are added to dq8 relative to dqs1.  00 No change in dq8 delay 01 Add dq8 delay of 1 delay unit. 10 Add dq8 delay of 2 delay units. 11 Add dq8 delay of 3 delay units.

**32.12.44 MMDC PHY Write DQ Byte2 Delay Register (MMDC\_MPWRDQBY2DL)**

This register is used to add fine-tuning adjustment to every bit in the write DQ byte2 relative to the write DQS

Address: 21B\_0000h base + 834h offset = 21B\_0834h

### MMDC\_MPWRDQBY2DL field descriptions

Field	Description
31–30 wr_dm2_del	Write dm2 delay fine-tuning. This field holds the number of delay units that are added to dm2 relative to dqs2.  00 No change in dm2 delay 01 Add dm2 delay of 1 delay unit. 10 Add dm2 delay of 2 delay units. 11 Add dm2 delay of 3 delay units.
29–28 wr_dq23_del	Write dq23 delay fine tuning. This field holds the number of delay units that are added to dq23 relative to dqs2.  00 No change in dq23 delay 01 Add dq23 delay of 1 delay unit. 10 Add dq23 delay of 2 delay units. 11 Add dq23 delay of 3 delay units.
27–26 Reserved	This read-only field is reserved and always has the value 0.
25–24 wr_dq22_del	Write dq22 delay fine tuning. This field holds the number of delay units that are added to dq22 relative to dqs2.  00 No change in dq22 delay 01 Add dq22 delay of 1 delay unit. 10 Add dq22 delay of 2 delay units. 11 Add dq22 delay of 3 delay units.
23–22 Reserved	This read-only field is reserved and always has the value 0.
21–20 wr_dq21_del	Write dq21 delay fine tuning. This field holds the number of delay units that are added to dq21 relative to dqs2.  00 No change in dq21 delay 01 Add dq21 delay of 1 delay unit. 10 Add dq21 delay of 2 delay units. 11 Add dq21 delay of 3 delay units.
19–18 Reserved	This read-only field is reserved and always has the value 0.
17–16 wr_dq20_del	Write dq20 delay fine tuning. This field holds the number of delay units that are added to dq20 relative to dqs2.  00 No change in dq20 delay 01 Add dq20 delay of 1 delay unit. 10 Add dq20 delay of 2 delay units. 11 Add dq20 delay of 3 delay units.
15–14 Reserved	This read-only field is reserved and always has the value 0.
13–12 wr_dq19_del	Write dq19 delay fine tuning. This field holds the number of delay units that are added to dq19 relative to dqs2.  00 No change in dq19 delay 01 Add dq19 delay of 1 delay unit.

Table continues on the next page...

**MMDC\_MPWRDQBY2DL field descriptions (continued)**

Field	Description
	10 Add dq19 delay of 2 delay units. 11 Add dq19 delay of 3 delay units.
11–10 Reserved	This read-only field is reserved and always has the value 0.
9–8 wr_dq18_del	Write dq18 delay fine tuning. This field holds the number of delay units that are added to dq18 relative to dqs2.  00 No change in dq18 delay 01 Add dq18 delay of 1 delay unit. 10 Add dq18 delay of 2 delay units. 11 Add dq18 delay of 3 delay units.
7–6 Reserved	This read-only field is reserved and always has the value 0.
5–4 wr_dq17_del	Write dq17 delay fine tuning. This field holds the number of delay units that are added to dq17 relative to dqs2.  00 No change in dq17 delay 01 Add dq17 delay of 1 delay unit. 10 Add dq17 delay of 2 delay units. 11 Add dq17 delay of 3 delay units.
3–2 Reserved	This read-only field is reserved and always has the value 0.
1–0 wr_dq16_del	Write dq16 delay fine tuning. This field holds the number of delay units that are added to dq16 relative to dqs2.  00 No change in dq16 delay 01 Add dq16 delay of 1 delay unit. 10 Add dq16 delay of 2 delay units. 11 Add dq16 delay of 3 delay units.

## 32.12.45 MMDC PHY Write DQ Byte3 Delay Register (MMDC\_MPWRDQBY3DL)

### MMDC\_MPWRDQBY3DL field descriptions

Field	Description
31–30 wr_dm3_del	Write dm3 delay fine tuning. This field holds the number of delay units that are added to dm3 relative to dqs3.  00 No change in dm3 delay 01 Add dm3 delay of 1 delay unit. 10 Add dm3 delay of 2 delay units. 11 Add dm3 delay of 3 delay units.
29–28 wr_dq31_del	Write dq31 delay fine tuning. This field holds the number of delay units that are added to dq31 relative to dqs3.  00 No change in dq31 delay 01 Add dq31 delay of 1 delay unit. 10 Add dq31 delay of 2 delay units. 11 Add dq31 delay of 3 delay units.
27–26 Reserved	This read-only field is reserved and always has the value 0.
25–24 wr_dq30_del	Write dq30 delay fine tuning. This field holds the number of delay units that are added to dq30 relative to dqs3.  00 No change in dq30 delay 01 Add dq30 delay of 1 delay unit. 10 Add dq30 delay of 2 delay units. 11 Add dq30 delay of 3 delay units.
23–22 Reserved	This read-only field is reserved and always has the value 0.
21–20 wr_dq29_del	Write dq29 delay fine tuning. This field holds the number of delay units that are added to dq29 relative to dqs3.

Table continues on the next page...

**MMDC\_MPWRDQBY3DL field descriptions (continued)**

Field	Description
	00 No change in dq29 delay 01 Add dq29 delay of 1 delay unit. 10 Add dq29 delay of 2 delay units. 11 Add dq29 delay of 3 delay units.
19–18 Reserved	This read-only field is reserved and always has the value 0.
17–16 wr_dq28_del	Write dq28 delay fine tuning. This field holds the number of delay units that are added to dq28 relative to dqs3.  00 No change in dq28 delay 01 Add dq28 delay of 1 delay unit. 10 Add dq28 delay of 2 delay units. 11 Add dq28 delay of 3 delay units.
15–14 Reserved	This read-only field is reserved and always has the value 0.
13–12 wr_dq27_del	Write dq27 delay fine tuning. This field holds the number of delay units that are added to dq27 relative to dqs3.  00 No change in dq27 delay 01 Add dq27 delay of 1 delay unit. 10 Add dq27 delay of 2 delay units. 11 Add dq27 delay of 3 delay units.
11–10 Reserved	This read-only field is reserved and always has the value 0.
9–8 wr_dq26_del	Write dq26 delay fine tuning. This field holds the number of delay units that are added to dq26 relative to dqs3.  00 No change in dq26 delay 01 Add dq26 delay of 1 delay unit. 10 Add dq26 delay of 2 delay units. 11 Add dq26 delay of 3 delay units.
7–6 Reserved	This read-only field is reserved and always has the value 0.
5–4 wr_dq25_del	Write dq25 delay fine tuning. This field holds the number of delay units that are added to dq25 relative to dqs3.  00 No change in dq25 delay 01 Add dq25 delay of 1 delay unit. 10 Add dq25 delay of 2 delay units. 11 Add dq25 delay of 3 delay units.
3–2 Reserved	This read-only field is reserved and always has the value 0.
1–0 wr_dq24_del	Write dq24 delay fine tuning. This field holds the number of delay units that are added to dq24 relative to dqs3.  00 No change in dq24 delay 01 Add dq24 delay of 1 delay unit.

*Table continues on the next page...*

### MMDC\_MPWRDQBY3DL field descriptions (continued)

Field	Description
10	Add dq24 delay of 2 delay units.
11	Add dq24 delay of 3 delay units.

## 32.12.46 MMDC PHY Read DQS Gating Control Register 0 (MMDC\_MPDGCTRL0)

Address: 21B\_0000h base + 83Ch offset = 21B\_083Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R																
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### MMDC\_MPDGCTRL0 field descriptions

Field	Description
31 RST_RD_FIFO	Reset Read Data FIFO and associated pointers. If this bit is asserted then the MMDC resets the read data FIFO and the associated pointers. This bit is self cleared after the FIFO reset is done.
30 DG_CMP_CYC	Read DQS gating sample cycle. If this bit is asserted then the MMDC waits 32 cycles before comparing the read data, Otherwise it waits 16 DDR cycles. 0 MMDC waits 16 DDR cycles 1 MMDC waits 32 DDR cycles
29 DG_DIS	Read DQS gating disable. If this bit is asserted then the MMDC disables the read DQS gating mechnism.

Table continues on the next page...

**MMDC\_MPDGCTRL0 field descriptions (continued)**

Field	Description
	<p>If this bits is asserted (read DQS gating is disabled) then pull-up and pull-down resistors suppose to be used on DQS and DQS# respectively</p> <p>0 Read DQS gating mechanism is enabled 1 Read DQS gating mechanism is disabled</p>
28 HW_DG_EN	<p>Enable automatic read DQS gating calibration. If this bit is asserted then the MMDC performs automatic read DQS gating calibration. HW negates this bit upon completion of the automatic read DQS gating.</p> <p>Note:</p> <p>Before issuing the first read command the MMDC counts 12 cycles.</p> <p>In LPDDR2 mode automatic (HW) read DQS gating should be disabled and Pull-up/pull-down resistors on DQS/DQS# should be enabled while ODT resistors must be disconnected.</p> <p>0 Disable automatic read DQS gating calibration 1 Start automatic read DQS gating calibration</p>
27–24 DG_HC_DEL1	<p>Read DQS gating half cycles delay for Byte1</p> <p>. This field indicates the delay in half cycles between read DQS gate and the middle of the read DQS preamble of Byte1. This delay is added to the delay that is generated by the read DQS1 gating delay-line, So the total read DQS gating delay is <math>(DG\_HC\_DEL\#)*0.5*\text{cycle} + (DG\_DL\_ABS\_OFFSET\#)*1/256*\text{cycle}</math></p> <p>Upon completion of the automatic read DQS gating calibration this field gets the value of the 4 MSB of <math>((HW\_DG\_LOW1 + HW\_DG\_UP1) / 2)</math>.</p> <p>0000 0 cycles delay. 0001 Half cycle delay. 0010 1 cycle delay 1101 6.5 cycles delay 1110 Reserved 1111 Reserved</p>
23 DG_EXT_UP	<p>DG extend upper boundary. By default the upper boundary of DQS gating HW calibration is set according to first failing comparison after at least one passing comparison. If this bit is asserted then the upper boundary is set according to the last passing comparison.</p>
22–16 DG_DL_ABS_OFFSET1	<p>Absolute read DQS gating delay offset for Byte1. This field indicates the absolute delay between read DQS gate and the middle of the read DQS preamble of Byte1 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be <math>(DG\_DL\_ABS\_OFFSET1 / 256)*\text{fast\_clk}</math>.</p> <p>This field can also bit written by HW. Upon completion of the automatic read DQS gating calibration this field gets the value of the 7 LSB of <math>((HW\_DG\_LOW1 + HW\_DG\_UP1) / 2)</math>.</p> <p>Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.</p>
15–13 Reserved	<p>This read-only field is reserved and always has the value 0.</p>
12 HW_DG_ERR	<p>HW DQS gating error. This bit valid is asserted when an error was found during the read DQS gating HW calibration process. Error can occur when no valid value was found during HW calibration.</p> <p>This bit is valid only after HW_DG_EN is de-asserted.</p> <p>0 No error was found during the DQS gating HW calibration process. 1 An error was found during the DQS gating HW calibration process.</p>

*Table continues on the next page...*

### MMDC\_MPDGCTRL0 field descriptions (continued)

Field	Description
11–8 DG_HC_DELO	<p>Read DQS gating half cycles delay for Byte0</p> <p>. This field indicates the delay in half cycles between read DQS gate and the middle of the read DQS preamble of Byte0/4. This delay is added to the delay that is generated by the read DQS1 gating delay-line, So the total read DQS gating delay is <math>(DG\_HC\_DEL\#)*0.5*\text{cycle} + (DG\_DL\_ABS\_OFFSET\#)*1/256*\text{cycle}</math></p> <p>Upon completion of the automatic read DQS gating calibration this field gets the value of the 4 MSB of <math>((HW\_DG\_LOW1 + HW\_DG\_UP1) / 2)</math>.</p> <p>0000 0 cycles delay.  0001 Half cycle delay.  0010 1 cycle delay  1101 6.5 cycles delay  1110 Reserved  1111 Reserved</p>
7 Reserved	This read-only field is reserved and always has the value 0.
6–0 DG_DL_ABS_OFFSET0	<p>Absolute read DQS gating delay offset for Byte0. This field indicates the absolute delay between read DQS gate and the middle of the read DQS preamble of Byte0 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be <math>(DG\_DL\_ABS\_OFFSET0 / 256)*\text{fast\_clk}</math>.</p> <p>This field can also bit written by HW. Upon completion of the automatic read DQS gating calibration this field gets the value of the 7 LSB of <math>((HW\_DG\_LOW0 + HW\_DG\_UP0) / 2)</math>.</p> <p>Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.</p>

## 32.12.47 MMDC PHY Read DQS Gating Control Register 1 (MMDC\_MPDGCTRL1)

Address: 21B\_0000h base + 840h offset = 21B\_0840h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0				DG_HC_DEL3				0	DG_DL_ABS_OFFSET3

### MMDC\_MPDGCTRL1 field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

**MMDC\_MPDGCTRL1 field descriptions (continued)**

Field	Description
27–24 DG_HC_DEL3	<p>Read DQS gating half cycles delay for Byte3</p> <p>. This field indicates the delay in half cycles between read DQS gate and the middle of the read DQS preamble of Byte3/7. This delay is added to the delay that is generated by the read DQS1 gating delay-line, So the total read DQS gating delay is <math>(DG\_HC\_DEL\#)*0.5*\text{cycle} + (DG\_DL\_ABS\_OFFSET\#)*1/256*\text{cycle}</math></p> <p>Upon completion of the automatic read DQS gating calibration this field gets the value of the 4 MSB of <math>((HW\_DG\_LOW3 + HW\_DG\_UP3) / 2)</math>.</p> <p>0000 0 cycles delay.  0001 Half cycle delay.  0010 1 cycle delay  1101 6.5 cycles delay  1110 Reserved  1111 Reserved</p>
23 Reserved	This read-only field is reserved and always has the value 0.
22–16 DG_DL_ABS_OFFSET3	<p>Absolute read DQS gating delay offset for Byte3. This field indicates the absolute delay between read DQS gate and the middle of the read DQS preamble of Byte3 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be <math>(DG\_DL\_ABS\_OFFSET3 / 256)*\text{fast\_clk}</math>.</p> <p>This field can also be written by HW. Upon completion of the automatic read DQS gating calibration this field gets the value of the 7 LSB of <math>((HW\_DG\_LOW3 + HW\_DG\_UP3) / 2)</math>.</p> <p>Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.</p>
15–12 Reserved	This read-only field is reserved and always has the value 0.
11–8 DG_HC_DEL2	<p>Read DQS gating half cycles delay for Byte2</p> <p>. This field indicates the delay in half cycles between read DQS gate and the middle of the read DQS preamble of Byte2/5. This delay is added to the delay that is generated by the read DQS1 gating delay-line, So the total read DQS gating delay is <math>(DG\_HC\_DEL\#)*0.5*\text{cycle} + (DG\_DL\_ABS\_OFFSET\#)*1/256*\text{cycle}</math></p> <p>Upon completion of the automatic read DQS gating calibration this field gets the value of the 4 MSB of <math>((HW\_DG\_LOW2 + HW\_DG\_UP2) / 2)</math>.</p> <p>0000 0 cycles delay.  0001 Half cycle delay.  0010 1 cycle delay  1101 6.5 cycles delay  1110 Reserved  1111 Reserved</p>
7 Reserved	This read-only field is reserved and always has the value 0.
6–0 DG_DL_ABS_OFFSET2	<p>Absolute read DQS gating delay offset for Byte2. This field indicates the absolute delay between read DQS gate and the middle of the read DQS preamble of Byte2 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be <math>(DG\_DL\_ABS\_OFFSET2 / 256)*\text{fast\_clk}</math>.</p> <p>This field can also be written by HW. Upon completion of the automatic read DQS gating calibration this field gets the value of the 7 LSB of <math>((HW\_DG\_LOW2 + HW\_DG\_UP2) / 2)</math>.</p>

*Table continues on the next page...*

**MMDC\_MPDGCTRL1 field descriptions (continued)**

Field	Description
	Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.

## 32.12.48 MMDC PHY Read DQS Gating delay-line Status Register (MMDC\_MPDGDLST0)

This register holds the status of the 4 dqs gating delay-lines.

Address: 21B\_0000h base + 844h offset = 21B\_0844h

### MMDC\_MPDGDLST0 field descriptions

Field	Description
31 -	This field is reserved. Reserved
30–24 DG_DL_UNIT_NUM3	This field reflects the number of delay units that are actually used by read DQS gating delay-line 3.
23 -	This field is reserved. Reserved
22–16 DG_DL_UNIT_NUM2	This field reflects the number of delay units that are actually used by read DQS gating delay-line 2.
15 -	This field is reserved. Reserved
14–8 DG_DL_UNIT_NUM1	This field reflects the number of delay units that are actually used by read DQS gating delay-line 1.
7 -	This field is reserved. Reserved
6–0 DG_DL_UNIT_NUM0	This field reflects the number of delay units that are actually used by read DQS gating delay-line 0.

## 32.12.49 MMDC PHY Read delay-lines Configuration Register (MMDC\_MPRDDLCTL)

This register controls read delay-lines functionality; it determines DQS delay relative to the associated DQ read access. The delay-line compensates for process variations and produces a constant delay regardless of the process, temperature and voltage.

Address: 21B\_0000h base + 848h offset = 21B\_0848h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**MMDC\_MPRDDLCTL field descriptions**

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–24 RD_DL_ABS_OFFSET3	<p>Absolute read delay offset for Byte3. This field indicates the absolute delay between read DQS strobe and the read data of Byte3 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be <math>(RD\_DL\_ABS\_OFFSET3 / 256) * fast\_clk</math>. So for the default value of 64 we get a quarter cycle delay.</p> <p>This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of <math>(HW\_RD\_DL\_LOW3 + HW\_RD\_DL\_UP3) / 2</math></p> <p>Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.</p>
23 Reserved	This read-only field is reserved and always has the value 0.
22–16 RD_DL_ABS_OFFSET2	<p>Absolute read delay offset for Byte2. This field indicates the absolute delay between read DQS strobe and the read data of Byte2 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be <math>(RD\_DL\_ABS\_OFFSET2 / 256) * fast\_clk</math>. So for the default value of 64 we get a quarter cycle delay.</p> <p>This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of <math>(HW\_RD\_DL\_LOW2 + HW\_RD\_DL\_UP2) / 2</math></p> <p>Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.</p>
15 Reserved	This read-only field is reserved and always has the value 0.
14–8 RD_DL_ABS_OFFSET1	<p>Absolute read delay offset for Byte1. This field indicates the absolute delay between read DQS strobe and the read data of Byte1 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be <math>(RD\_DL\_ABS\_OFFSET1 / 256) * fast\_clk</math>. So for the default value of 64 we get a quarter cycle delay.</p> <p>This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of <math>(HW\_RD\_DL\_LOW1 + HW\_RD\_DL\_UP1) / 2</math></p> <p>Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.</p>
7 Reserved	This read-only field is reserved and always has the value 0.
6–0 RD_DL_ABS_OFFSET0	<p>Absolute read delay offset for Byte0. This field indicates the absolute delay between read DQS strobe and the read data of Byte0 with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be <math>(RD\_DL\_ABS\_OFFSET0 / 256) * fast\_clk</math>. So for the default value of 64 we get a quarter cycle delay.</p> <p>This field can also bit written by HW. Upon completion of the read delay-line HW calibration this field gets the value of <math>(HW\_RD\_DL\_LOW0 + HW\_RD\_DL\_UP0) / 2</math></p> <p>Note that not all changes will have effect on the actual delay. If the requested change is smaller than the delay-line resolution, then no change will occur.</p>

## 32.12.50 MMDC PHY Read delay-lines Status Register (MMDC\_MPRDDLST)

This register holds the status of the 4 read delay-lines.

Address: 21B\_0000h base + 84Ch offset = 21B\_084Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	RD_DL_UNIT_NUM3							0	RD_DL_UNIT_NUM2

### MMDC\_MPRDDLST field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–24 RD_DL_UNIT_NUM3	This field reflects the number of delay units that are actually used by read delay-line 3.
23 Reserved	This read-only field is reserved and always has the value 0.
22–16 RD_DL_UNIT_NUM2	This field reflects the number of delay units that are actually used by read delay-line 2.
15 Reserved	This read-only field is reserved and always has the value 0.
14–8 RD_DL_UNIT_NUM1	This field reflects the number of delay units that are actually used by read delay-line 1.
7 Reserved	This read-only field is reserved and always has the value 0.
6–0 RD_DL_UNIT_NUM0	This field reflects the number of delay units that are actually used by read delay-line 0.

## 32.12.51 MMDC PHY Write delay-lines Configuration Register (MMDC\_MPWRDLCTL)

This register controls write delay-lines functionality, it determines DQ/DM delay relative to the associated DQS in write access. The delay-line compensates for process variations, and produces a constant delay regardless of the process, temperature and voltage.

Address: 21B\_0000h base + 850h offset = 21B\_0850h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

32.12.55 MMDC PHY Read Delay HW Calibration Control Register (MMDC\_MPRDDLHWCTL)

Address: 21B\_0000h base + 860h offset = 21B\_0860h

MMDC\_MPRDDLHWCTL field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

**MMDC\_MPRDDLHWCTL field descriptions (continued)**

<b>Field</b>	<b>Description</b>
5 HW_RD_DL_CMP_CYC	Automatic (HW) read sample cycle. If this bit is asserted then the MMDC will compare the read data 32 cycles after the MMDC sent the read command enable pulse else it compares the data after 16 cycles.
4 HW_RD_DL_EN	Enable automatic (HW) read calibration. If this bit is asserted then the MMDC will perform an automatic read calibration. HW should negate this bit upon completion of the calibration. Negation of this bit also points that the read calibration results are valid  Note: Before issuing the first read command MMDC counts 12 cycles.
3 HW_RD_DL_ERR3	Automatic (HW) read calibration error of Byte3. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 3. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST1 register. This bit is valid only after HW_RD_DL_EN is de-asserted.  0 No error was found in read delay-line 3 during the automatic (HW) read calibration process of read delay-line 3. 1 An error was found in read delay-line 3 during the automatic (HW) read calibration process of read delay-line 3.
2 HW_RD_DL_ERR2	Automatic (HW) read calibration error of Byte2. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 2. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST1 register. This bit is valid only after HW_RD_DL_EN is de-asserted.  0 No error was found in read delay-line 2 during the automatic (HW) read calibration process of read delay-line 2. 1 An error was found in read delay-line 2 during the automatic (HW) read calibration process of read delay-line 2.
1 HW_RD_DL_ERR1	Automatic (HW) read calibration error of Byte1. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 1. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST0 register. This bit is valid only after HW_RD_DL_EN is de-asserted.  0 No error was found in read delay-line 1 during the automatic (HW) read calibration process of read delay-line 1. 1 An error was found in read delay-line 1 during the automatic (HW) read calibration process of read delay-line 1.
0 HW_RD_DL_ERR0	Automatic (HW) read calibration error of Byte0. If this bit is asserted then it indicates that an error was found during the HW calibration process of read delay-line 0. In case this bit is zero at the end of the calibration process then the boundary results can be found at MPRDDLHWST0 register. This bit is valid only after HW_RD_DL_EN is de-asserted.  0 No error was found in read delay-line 0 during the automatic (HW) read calibration process of read delay-line 0. 1 An error was found in read delay-line 0 during the automatic (HW) read calibration process of read delay-line 0.

32.12.56 MMDC PHY Write Delay HW Calibration Control Register (MMDC\_MPWRDLHWCTL)

Address: 21B\_0000h base + 864h offset = 21B\_0864h

MMDC\_MPWRDLHWCTL field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value 0.
5 HW_WR_DL_CMP_CYC	Write sample cycle. If this bit is asserted then the MMDC will compare the data 32 cycles after the MMDC sent the read command enable pulse else it compares the data after 16 cycles.
4 HW_WR_DL_EN	Enable automatic (HW) write calibration. If this bit is asserted then the MMDC will perform an automatic write calibration. HW should negate this bit upon completion of the calibration. **MMDC\_MPWLHWERR field descriptions**

Field	Description
31–24 HW_WL3_DQ	HW write-leveling calibration result of Byte3. This field holds the results for all the 8 write-leveling steps of Byte3. i.e bit 0 holds the result of the write-leveling calibration of 0 delay, bit 1 holds the result of the write-leveling calibration of 1/8delay till bit 7 that holds the result of the write-leveling calibration of 7/8 delay
23–16 HW_WL2_DQ	HW write-leveling calibration result of Byte2. This field holds the results for all the 8 write-leveling steps of Byte2. i.e bit 0 holds the result of the write-leveling calibration of 0 delay, bit 1 holds the result of the write-leveling calibration of 1/8delay till bit 7 that holds the result of the write-leveling calibration of 7/8 delay
15–8 HW_WL1_DQ	HW write-leveling calibration result of Byte1. This field holds the results for all the 8 write-leveling steps of Byte1. i.e bit 0 holds the result of the write-leveling calibration of 0 delay, bit 1 holds the result of the write-leveling calibration of 1/8delay till bit 7 that holds the result of the write-leveling calibration of 7/8 delay
7–0 HW_WL0_DQ	HW write-leveling calibration result of Byte0. This field holds the results for all the 8 write-leveling steps of Byte0. i.e bit 0 holds the result of the write-leveling calibration of 0 delay, bit 1 holds the result of the write-leveling calibration of 1/8delay till bit 7 that holds the result of the write-leveling calibration of 7/8 delay

31–27 -	This field is reserved. Reserved
26–16 HW_DG_UP3	HW DQS gating calibration result of the upper boundary of Byte3. This field holds the HW DQS gating calibration result of the upper boundary of Byte3.
15–11 -	This field is reserved. Reserved
10–0 HW_DG_LOW3	HW DQS gating calibration result of the lower boundary of Byte3. This field holds the HW DQS gating calibration result of the lower boundary of Byte3.

### 32.12.66 MMDC PHY Pre-defined Compare Register 1 (MMDC\_MPPDCMPR1)

This register holds the MMDC pre-defined compare value that will be used during automatic read, read DQS gating and write calibration process. The compare value can be the MPR value (as defined in the JEDEC) or can be programmed by the PDV1 and PDV2 fields. In case of DDR3 (BL=8) the MMDC will duplicate PDV1,PDV2 and drive that data on Beat4-7 of the same byte

Address: 21B\_0000h base + 88Ch offset = 21B\_088Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	PDV2																PDV1

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### MMDC\_MPPDCMPR1 field descriptions

Field	Description
31–16 PDV2	MMDC Pre defined compare value2. This field holds the 2 MSB of the data that will be driven to the DDR device during automatic read, read DQS gating and write calibrations in case MPR(DDR3)/ DQ calibration (LPDDR2) mode are disabled (MPR_CMP is disabled). Upon read access during the calibration the MMDC will compare the read data with the data that is stored in this field.  Note : Before issue the read access the MMDC will invert the value of this field and drive it to the associate entry in the read comparison FIFO. For further information see Section 19.14.3.1.2, "Calibration with pre-defined value", Section 19.14.4.1.2, "Calibration with pre-defined value and Section 19.14.5.1, "HW (automatic) Write Calibraion
15–0 PDV1	MMDC Pre defined compare value2. This field holds the 2 LSB of the data that will be driven to the DDR device during automatic read, read DQS gating and write calibrations in case MPR(DDR3)/ DQ calibration (LPDDR2) mode are disabled (MPR_CMP is disabled). Upon read access during the calibration the MMDC will compare the read data with the data that is stored in this field.  <b>NOTE:</b> Before issuing the read access, the MMDC will invert the value of this field and drive it to the associated entry in the read comparison FIFO.

## 32.12.67 MMDC PHY Pre-defined Compare and CA delay-line Configuration Register (MMDC\_MPPDCMPR2)

Address: 21B\_0000h base + 890h offset = 21B\_0890h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16		
R	0	PHY_CA_DL_UNIT												0				
W															CA_DL_ABS_OFFSET			
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0		

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
R	0														READ_LEVEL_PATTERN		MPR_FULL_CMP	MPR_CMP
W																		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		

**MMDC\_MPPDCMPR2 field descriptions**

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30–24 PHY_CA_DL_UNIT	This field reflects the number of delay units that are actually used by CA (Command/Address of LPDDR2) delay-line
23 Reserved	This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

### MMDC\_MPPDCMPR2 field descriptions (continued)

Field	Description
22–16 CA_DL_ABS_OFFSET	Absolute CA (Command/Address of LPDDR2) offset. This field indicates the absolute delay between CA (Command/Address) bus and the DDR clock (CK) with fractions of a clock period and up to half cycle. The fraction is process and frequency independent. The delay of the delay-line would be $(CA\_DL\_ABS\_OFFSET / 256) * fast\_clk$ . So for the default value of 64 we get a quarter cycle delay.
15–3 Reserved	This read-only field is reserved and always has the value 0.
2 READ_LEVEL_PATTERN	MPR(DDR3)/DQ calibration(LPDDR2) read compare pattern. In case MPR(DDR3)/DQ calibration(LPDDR2) modes are used during the calibration process (MPR_CMP is asserted) then this field indicates the read pattern for the comparison.  0 Compare with read pattern 1010 1 Compare with read pattern 0011 (Used only in LPDDR2 mode)
1 MPR_FULL_CMP	MPR(DDR3)/DQ calibration (LPDDR2) full compare enable. In case MPR(DDR3)/DQ calibration(LPDDR2) modes are used during the calibration process (MPR_CMP is asserted) then this field indicates whether the MMDC will compare all the bits of the data that is read from the DDR device to the MPR pre-defined pattern. When this bit is de-asserted only LSB of each byte is compared.
0 MPR_CMP	MPR(DDR3)/DQ calibration (LPDDR2) compare enable. This bit indicates whether the MMDC will compare the read data during automatic read and read DQS calibration processes to the pre-defined patterns that are driven by the DDR device (READ_LEVEL_PATTERN as defined by JEDEC) or general pre-defined value that are stored in PDV1 and PDV2. When this bit is disabled data is compared to the data of the pre defined compare value field  For further information see <a href="#">Read DQS Gating Calibration</a> and <a href="#">Read Calibration</a> .

### 32.12.68 MMDC PHY SW Dummy Access Register (MMDC\_MPSWDAR0)

Address: 21B\_0000h base + 894h offset = 21B\_0894h

MMDC\_MPSWDAR0 field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

**MMDC\_MPSWDAR0 field descriptions (continued)**

Field	Description
5 SW_DUM_CMP3	SW dummy read byte3 compare results. This bit indicates the result of the read data comparison of Byte3 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-asserted.  0 Dummy read fail 1 Dummy read pass
4 SW_DUM_CMP2	SW dummy read byte2 compare results. This bit indicates the result of the read data comparison of Byte2 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-asserted.  0 Dummy read fail 1 Dummy read pass
3 SW_DUM_CMP1	SW dummy read byte1 compare results. This bit indicates the result of the read data comparison of Byte1 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-asserted.  0 Dummy read fail 1 Dummy read pass
2 SW_DUM_CMP0	SW dummy read byte0 compare results. This bit indicates the result of the read data comparison of Byte0 at the completion of SW_DUMMY_RD. This bit is valid only when SW_DUMMY_RD is de-asserted.  0 Dummy read fail 1 Dummy read pass
1 SW_DUMMY_RD	SW dummy read. When this bit is asserted the MMDC will generate internally read access without intervention of the system toward bank 0, row 0, column 0. If MPR_CMP = 1 then the read data will be compared to MPPDCMPR2[READ_LEVEL_PATTERN]. If MPR_CMP = 0 then the read data will be compared to MPPDCMPR1[PDV1], MPPDCMPR1[PDV2]. Upon completion of the access this bit is de-asserted automatically and the read data and comparison results are valid at MPSWDAR0[SW_DUM_CMP#] and MPSWDRDR0-MPSWDRDR7 respectively.
0 SW_DUMMY_WR	SW dummy write. When this bit is asserted the MMDC will generate internally write access without intervention of the system toward bank 0, row 0, column 0, while the data is driven from MPPDCMPR1[PDV1] and MPPDCMPR1[PDV2]. The bit is de-asserted automatically upon completion of the access.

### MMDC\_MPMUR0 field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value 0.
25–16 MU_UNIT_DEL_NUM	Number of delay units measured per cycle. This field is used in debug mode and holds the number of delay units that were measured by the measure unit per DDR clock cycle. The delay-lines that are used in every calibration process use that number for generating the desired delay.
15–12 Reserved	This read-only field is reserved and always has the value 0.
11 FRC_MSR	Force measurement on delay-lines. When this bit is asserted then a measurement process will be performed, where at the completion of the process the delay-lines will issue the desired delay. Upon completion of the measurement process the measure unit and the delay-lines will return to functional mode. This bit is self cleared.  <b>NOTE:</b> This bit should be used only during manual (SW) calibration and not while the DDR is functional (being accessed). After initial calibration is done the hardware performs periodic measurements to track any operating conditions changes. Hence, force measurements (FRC_MSR) should not be used. See <a href="#">Calibration Process</a> for more information.  <b>NOTE:</b> User should make sure that there is no active accesses to/from DDR before asserting this bit.  0 No measurement is performed 1 Perform measurement process
10 MU_BYP_EN	Measure unit bypass enable. This field is used in debug mode and when it is asserted then the delay-lines will use the number of delay units that are indicated at MU_BYP_VAL, otherwise the delay-lines will use the number of delay units that was measured by the measurement unit and are indicated at MU_UNIT_DEL_NUM  0 The delay-lines use delay units as indicated at MU_UNIT_DEL_NUM. 1 The delay-lines use delay units as indicated at MU_BYPASS_VAL.
9–0 MU_BYP_VAL	Number of delay units for measurement bypass. This field is used in debug mode and holds the number of delay units that will be used by the delay-lines when MU_BYP_EN is asserted.

### 32.12.78 MMDC Write CA delay-line controller (MMDC\_MPWRCADL)

This register is used to add fine-tuning adjustment to the CA (command/Address of LPDDR2 bus) relative to the DDR clock

Address: 21B\_0000h base + 8BCh offset = 21B\_08BCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

#### MMDC\_MPWRCADL field descriptions

Field	Description
31–20 Reserved	This read-only field is reserved and always has the value 0.
19–18 WR_CA9_DEL	CA (Command/Address LPDDR2 bus) bit 9 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 9 relative to the clock.  00 No change in CA9 delay 01 Add CA9 delay of 1 delay unit 10 Add CA9 delay of 2 delay units. 11 Add CA9 delay of 3 delay units.
17–16 WR_CA8_DEL	CA (Command/Address LPDDR2 bus) bit 8 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 8 relative to the clock.  00 No change in CA8 delay 01 Add CA8 delay of 1 delay unit 10 Add CA8 delay of 2 delay units. 11 Add CA8 delay of 3 delay units.
15–14 WR_CA7_DEL	CA (Command/Address LPDDR2 bus) bit 7 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 7 relative to the clock.  00 No change in CA7 delay 01 Add CA7 delay of 1 delay unit 10 Add CA7 delay of 2 delay units. 11 Add CA7 delay of 3 delay units.
13–12 WR_CA6_DEL	CA (Command/Address LPDDR2 bus) bit 6 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 6 relative to the clock.  00 No change in CA6 delay

Table continues on the next page...

### MMDC\_MPWRCADL field descriptions (continued)

Field	Description
	01 Add CA6 delay of 1 delay unit 10 Add CA6 delay of 2 delay units. 11 Add CA6 delay of 3 delay units.
11–10 WR_CA5_DEL	CA (Command/Address LPDDR2 bus) bit 5 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 5 relative to the clock.  00 No change in CA5 delay 01 Add CA5 delay of 1 delay unit 10 Add CA5 delay of 2 delay units. 11 Add CA5 delay of 3 delay units.
9–8 WR_CA4_DEL	CA (Command/Address LPDDR2 bus) bit 4 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 4 relative to the clock.  00 No change in CA4 delay 01 Add CA4 delay of 1 delay unit 10 Add CA4 delay of 2 delay units. 11 Add CA4 delay of 3 delay units.
7–6 WR_CA3_DEL	CA (Command/Address LPDDR2 bus) bit 3 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 3 relative to the clock.  00 No change in CA3 delay 01 Add CA3 delay of 1 delay unit 10 Add CA3 delay of 2 delay units. 11 Add CA3 delay of 3 delay units.
5–4 WR_CA2_DEL	CA (Command/Address LPDDR2 bus) bit 2 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 2 relative to the clock.  00 No change in CA2 delay 01 Add CA2 delay of 1 delay unit 10 Add CA2 delay of 2 delay units. 11 Add CA2 delay of 3 delay units.
3–2 WR_CA1_DEL	CA (Command/Address LPDDR2 bus) bit 1 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 1 relative to the clock.  00 No change in CA1 delay 01 Add CA1 delay of 1 delay unit 10 Add CA1 delay of 2 delay units. 11 Add CA1 delay of 3 delay units.
1–0 WR_CA0_DEL	CA (Command/Address LPDDR2 bus) bit 0 delay fine tuning. This field holds the number of delay units that are added to CA (Command/Address bus) bit 0 relative to the clock.  00 No change in CA0 delay 01 Add CA0 delay of 1 delay unit 10 Add CA0 delay of 2 delay units. 11 Add CA0 delay of 3 delay units.

### 32.12.79 MMDC Duty Cycle Control Register (MMDC\_MPDCCR)

This register is used to control the duty cycle of the DQS and the primary clock (CK0) . Programming of that register is permitted by entering the DDR device into self-refresh mode through LPMD/DVFS mechanism

Address: 21B\_0000h base + 8C0h offset = 21B\_08C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

# Chapter 33

## Network Interconnect Bus System (NIC-301)

### 33.1 Overview

This section provides an overview of the NIC-301 (Network Inter-Connect) AXI arbiter IP.

The NIC-301 (by ARM Ltd.) is a configurable AXI arbiter between several masters and slaves. The NIC-301 IP is designed so that many configuration options are selected at the hardware design stage, determined by SoC characteristics and needs, while several other configuration options are software-controlled.

This chapter covers in brief the NIC-301 functionality, while providing configuration details on the NIC-301 instances used in the chip. For complete details on the NIC-301 design, see the ARM specification, *AMBA® Network Interconnect (NIC-301) Technical Reference Manual*.

#### NOTE

The NIC-301 default settings are configured by Freescale's board support package (BSP), and in most cases should not be modified by the customer. The default settings have gone through exhaustive testing during the validation of the part, and have proven to work well for the part's intended target applications. Changes to the default settings may result in a degradation in system performance.

### 33.2 Block diagram

The NIC-301 AXI arbiter (or "CoreLink Network Interconnect") by ARM, provides configurable AXI-based interconnect logic, for connecting a number of masters (initiators) to several slaves (targets), via a configurable bus switches and bridging components.

The bus system is composed of three such instances: PER1, PER2, and FAST.

Each instance can include one or more bus switches, with additional logic.

This chapter provides details of the various instances and the selected configuration parameters.

The top level diagram of the bus system is shown in the following figure.

**Figure 33-1. NIC-301 Bus System**

**33.2.1 NIC-301 Main Features**

Key features of the NIC-301 module include the following:

- Address space memory mapping, including 'remap' functions.
- Programmer's view, for software-configured parameters, via "GPV" ports.
- Support for cross-clock domain synchronization.

**33.2.2 Modes and Operations**

The NIC-301 supports a normal functional mode only, as described in [Normal Mode](#).

**33.3 External Signals**

The NIC-301 has no external I/O interfaces.

**33.4 Memory Map and Register Definition**

This section includes the block memory map and detailed register descriptions.

Access to NIC-301 registers is provided through the global programmer's view (GPV) ports. Each GPV port provides access to the configuration registers of certain IP . The GPV base addresses are listed in the table below:

**Table 33-1. GPV ports memory allocations**

GPV	Associated NIC-301	System Bus	Chip Address	
			Start	End
GPV_0	FAST	Main DDR Arbitration	00B0_0000	00BF_FFFF

*Table continues on the next page...*

**Table 33-1. GPV ports memory allocations (continued)**

GPV	Associated NIC-301	System Bus	Chip Address	
			Start	End
GPV_1	PER1	Peripheral AHB/AXI Arbitration	00C0_0000	00CF_FFFF
GPV_2	PER2	Peripheral AHB/AXI Arbitration	00D0_0000	00DF_FFFF

### 33.4.1 Memory Map

The NIC-301 memory map, is dependent on the selected configuration option at time of creation.

A "template" map is provided in [Table 33-2](#) below. For specific features, refer to the configuration tables in [NIC Specific Parameters](#) to see which specific options are selected.

### 33.4.2 Configuration programmers model

The GPV's contain configuration registers, partitioned into a number of individual 4KB blocks.

The general structure of the registers is provided by the following tables:

- Address map of the programmers model, [Table 33-2](#)
- AMIB Registers, [Table 33-3](#)
- ASIB Registers, [Table 33-4](#)

**Table 33-2. Address map of the programmers model**

Address Offset from Base Address	Registers	Notes
0x000F_F000	Internal interface p registers	Maximum p = 61 Note <sup>1</sup>
	...	
0x000C_4000	Internal interface 2 registers	
0x000C_3000	Internal interface 1 registers	
0x000C_2000	Internal interface 0 registers	

*Table continues on the next page...*

**Table 33-2. Address map of the programmers model (continued)**

Address Offset from Base Address	Registers	Notes
0x000C_1000	Slave interface m registers	Maximum m = 127
	...	Note <sup>2</sup>
0x0004_4000	Slave interface 2 registers	
0x0004_3000	Slave interface 1 registers	
0x0004_2000	Slave interface 0 registers	
0x0004_1000	Master interface n registers	Maximum n = 63
	...	Note <sup>3</sup>
0x0000_4000	Master interface 2 registers	
0x0000_3000	Master interface 1 registers	
0x0000_2000	Master interface 0 registers	
0x0000_1000	ID registers	
0x0000_0000	Address control registers	Configurable base address <sup>4</sup>

1. Index refers to BI registers index
2. Index refer to ASIB registers index
3. Index refer to AMIB registers index
4. Reserved for internal use

### 33.4.2.1 Address control and ID registers

Registers at offsets 0x0–0xFFC are reserved for internal use.

### 33.4.2.2 AMBA master interface block (AMIB) configuration registers

The table below lists only the registers that affect the user. All other addresses are treated as "reserved".

**Table 33-3. AMIB Registers**

Offset	Register	Access	Width	Reset Value
0x024	fn_mod2 Bypass merge. This register is only present if upsizing or downsizing. See upsizing/downsizing data width functions in AMBA Network Interconnect TRM.	RW	1	0
0x040	wr_tidemark	RW	4	Note <sup>1</sup>

1. Reset value varies, default value chosen at RTL creation time is designed to suit normal operation.

### 33.4.2.3 ASIB (AMBA slave interface block) configuration registers

The table below lists only the registers that affect the user. All other addresses are treated as "reserved".

**Table 33-4. ASIB Registers**

Offset	Register	Access	Width	Reset Value
0x040	wr_tidemark Valid only for AXI slaves with WFIFO >=4.	RW	4	Note <sup>1</sup>
0x100	read_qos	RW	4	Note <sup>2</sup>
0x104	write_qos	RW	4	Note4

1. Reset value varies, default value chosen at RTL creation time is designed to suit typical operation cases.
2. QoS default is set at RTL creation time, and is listed in specific NIC-301 configuration tables in [NIC-specific parameters](#), as parameters "QoS qv\_value" in ASIB / AMIB parameter tables.

### 33.4.3 Register Descriptions

The NIC-301 registers are dependent upon the selected configuration, the type of ports, hardware-selected features and whether they have a GPV view. The addressing is associated to a specific port, by looking at the port's index number, under "apb\_slave" column.

The memory map template is provided in the [Configuration programmers model](#) above.

### 33.4.4 NIC Specific Parameters

This section details the configuration parameters of the NIC-301.

General notes:

1. The associated Master / Slave port interface ID (for each "GPV\_N") is specified by the "apb\_slave" / "apb\_master" <sup>1</sup> index. The Slave/Master interface, configuration registers start address is obtained by the following:

Start address (for "apb" index= "n") = GPV\_N base + (n \* 0x1000).

2. For the MX6FAST, QoS (Quality Of Service) is controlled by the QoS block and not by the GPV registers.
3. The security features of NIC-301 are not used, since master-slaves permissions are controlled by the CSU security policy/scheme.

---

1. "APB" stands for "ARM Peripheral Bus".

Table 33-5. NIC-301 parameters

Master	apb_slave	Tidemark	QOS qv_value	Comments
Configured via GPV_1 port				
DAP	72		2	
SDMA Burst	66		3	
SDMA Peripheral	67		3	
DCP	68		2

MPCore-1	67		QoS input control signal	
EPDC or SiPix (depends on fuse)	70	12	QoS input control signal	
LCDIF	72		QoS input control signal	
PXP	73	12	QoS input control signal	
GPU	74		QoS input control signal	

## Chapter 34

# On-Chip OTP Controller (OCOTP\_CTRL)

### 34.1 Overview

This section contains information describing the requirements for the on-chip eFuse OTP controller along with details about the block functionality and implementation.

In this document, the words "eFuse" and "OTP" are interchangeable. OCOTP refers to the hardware block itself.

#### 34.1.1 Features

The OCOTP provides the following features :

- 32-bit word restricted program and read to 2Kbits of eFuse OTP(128x8).
- Loading and housing of fuse content into shadow registers.
- memory-mapped (restricted) access to 2Kbits of shadow registers.
- Generation of hwv\_fuse (hardware visible fuse bus) and the hwv\_reg bus which is made of up of volatile PIO register based "fuses". The hwv\_reg bits come from the SCS (Software Controllable Signals) register.
- Generation of sticky\_reg which is consist of sticky register bits.
- Provide program-protect and read-protect efuse.
- Provide override and read protection of shadow register.
- CRC32 test for read-lock fuse content.

### 34.2 Clocks

The table found here describes the clock sources for OCOTP.

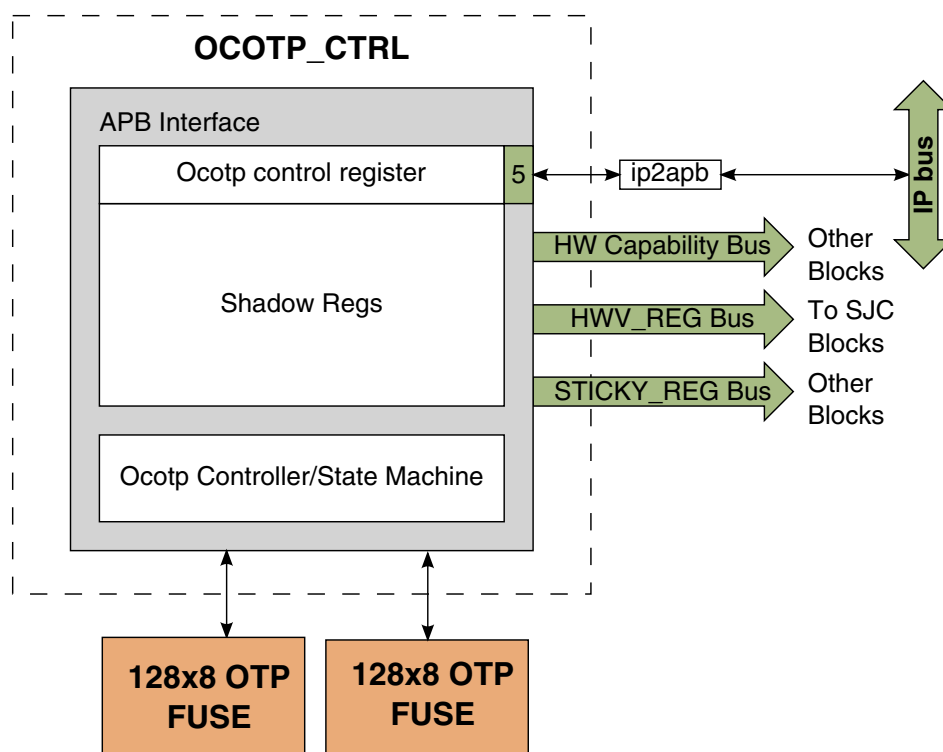

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 34-1. OCOTP Clocks**

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

## 34.3 Top-Level Symbol and Functional Overview

The figure found here shows the OCOTP system level diagram.

**Figure 34-1. OCOTP System Level Diagram**

### 34.3.1 Operation

The IP bus interface of the OCOTP provides two functions.

- Configure control registers for programming and reading fuse word.
- Override and read shadow registers.

For efuse, program can only be performed on bit and read is based on byte. OCOTP configuration for program and read are performed on 32-bit words for SW convenience. For writes, the 32-bit word reflects the "write-mask". Bit fields with 0 will not be programmed and bit fields with 1 will be programmed. OCOTP will program bit field with 1 in the fuse word one bit by one bit. For reads, OCOTP will read 4 times to get 4 bytes in the fuse word in order.

In this document, 2k bits fuse are divided into 8 banks by function. Each bank has 8 fuse words. In physical, 2k bits fuse are in two 128x8 efusebox.

### 34.3.1.1 Shadow Register Reload

All fuse words in efusebox are shadowed. Therefore, fuse information is available through memory mapped shadow registers. If fuses are subsequently programmed, the shadow registers should be reloaded to keep them coherent with the fuse bank arrays.

The "reload shadows" feature allows the user to force a reload of the shadow registers (including HW\_OCOTP\_LOCK) without having to reset the device. To force a reload, complete the following steps:

1. Set the HW\_OCOTP\_TIMING[STROBE\_READ] and HW\_OCOTP\_TIMING[RELAX] field value appropriately (as explained in a later section).
2. Check that HW\_OCOTP\_CTRL[BUSY] and HW\_OCOTP\_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a new access can be requested.
3. Set the HW\_OCOTP\_CTRL[RELOAD\_SHADOWS] bit. OCOTP will read all the fuse one by one and put it into corresponding shadow register.
4. Wait for HW\_OCOTP\_CTRL[BUSY] and HW\_OCOTP\_CTRL[RELOAD\_SHADOWS] to be cleared by the controller.

The controller will automatically clear the HW\_OCOTP\_CTRL[RELOAD\_SHADOWS] bit after the successful completion of the operation.

### 34.3.1.2 Fuse and Shadow register read

All shadow registers are always readable through the APB bus except some secret keys regions. When their corresponding fuse lock bits are set, the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA.

In addition HW\_OCOTP\_CTRL[ERROR] will be set. It must be cleared by software before any new write, read or reload access can be issued. Subsequent reads to unlocked shadow locations will still work successfully however.

To read fuse word directly from fusebox correctly complete the following steps:

1. Program HW\_OCOTP\_TIMING[STROBE\_READ] and HW\_OCOTP\_TIMING[RELAX] fields with timing values to match the current frequency of the ipg\_clk. OTP read will work at maximum bus frequencies as long as the HW\_OCOTP\_TIMING parameters are set correctly.
2. Check that HW\_OCOTP\_CTRL[BUSY] and HW\_OCOTP\_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a read access can be requested.
3. Write the requested address to HW\_OCOTP\_CTRL[ADDR].
4. Set HW\_OCOTP\_READ\_CTRL[READ\_FUSE] to 1. OCOTP will auto read 4 bytes in requested word address in fusebox one by one. Then put read value into HW\_OCOTP\_READ\_FUSE\_DATA register.
5. Once complete, the controller will clear BUSY. A read request to a protected or locked region will result in no OTP access and no setting of HW\_OCOTP\_CTRL[BUSY]. In addition HW\_OCOTP\_CTRL[ERROR] will be set. It must be cleared by software before any new access can be issued.
6. Read HW\_OCOTP\_READ\_FUSE\_DATA register to get fuse word value. HW\_OCOTP\_READ\_FUSE\_DATA will be 0xBADABADA when HW\_OCOTP\_CTRL[ERROR] is set.

### 34.3.1.3 Fuse and Shadow Register Writes

Shadow register bits can be overridden by software until the corresponding fuse lock bit for the region is set. When the lock shadow bit is set, the shadow registers for that lock region become write locked. The LOCK shadow register also has no shadow or fuse lock bits but it is always read only.

In order to avoid "rogue" code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To program fuse bank correctly complete the following steps:

1. Program HW\_OCOTP\_TIMING[STROBE\_PROG] and HW\_OCOTP\_TIMING[RELAX] fields with timing values to match the current frequency of the ipg\_clk. OTP writes will work at maximum bus frequencies as long as the HW\_OCOTP\_TIMING parameters are set correctly.

2. Check that HW\_OCOTP\_CTRL[BUSY] and HW\_OCOTP\_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write or reload must be completed before a write access can be requested.
3. Write the requested address to HW\_OCOTP\_CTRL[ADDR] and program the unlock code into HW\_OCOTP\_CTRL[WR\_UNLOCK]. This must be programmed for each write access. The lock code is documented in the register description. Both the unlock code and address can be written in the same operation.
4. Write the data to the HW\_OCOTP\_DATA register. This will automatically set HW\_OCOTP\_CTRL[BUSY] and clear HW\_OCOTP\_CTRL[WR\_UNLOCK]. To protect programming same OTP bit twice, before program OCOTP will automatically read fuse value in OTP and use read value to mask program data. The controller will use masked program data to program a 32-bit word in the OTP per the address in HW\_OCOTP\_CTRL[ADDR]. Bit fields with 1's will result in that OTP bit being programmed. Bit fields with 0's will be ignored. At the same time that the write is accepted, the controller makes an internal copy of HW\_OCOTP\_CTRL[ADDR] which cannot be updated until the next write sequence is initiated. This copy guarantees that erroneous writes to HW\_OCOTP\_CTRL[ADDR] will not affect an active write operation. It should also be noted that during the programming HW\_OCOTP\_DATA will shift right (with zero fill). This shifting is required to program the OTP serially. During the write operation, HW\_OCOTP\_DATA cannot be modified.
5. Once complete, the controller will clear BUSY. A write request to a protected or locked region will result in no OTP access and no setting of HW\_OCOTP\_CTRL[BUSY]. In addition HW\_OCOTP\_CTRL[ERROR] will be set. It must be cleared by software before any new write access can be issued.

It should be noted that write latencies to OTP are numbers of 10 micro-seconds per word. Write latencies will be based on amount of bit filed which is 1. For example : program half fuse bits in one word need 10us x 16.

For further details of OTP read/write operations see [eFUSE].

HW\_OCOTP\_CTRL[ERROR] will be set under the following conditions:

- A write is performed to a shadow register during a shadow reload (essentially, while HW\_OCOTP\_CTRL[RELOAD\_SHADOWS] is set. In addition, the contents of the shadow register shall not be updated.
- A write is performed to a shadow register which has been locked.
- A read is performed to from a shadow register which has been read locked.
- A program is performed to a fuse word which has been locked.
- A read is performed to from a fuse word which has been read locked.

### 34.3.1.4 Write Postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations following a write must be separated by 2 us after the clearing of HW\_OCOTP\_CTRL\_BUSY following the write. This guarantees programming voltages on-chip to reach a steady state when exiting a write sequence. This includes reads, shadow reloads, or other writes.

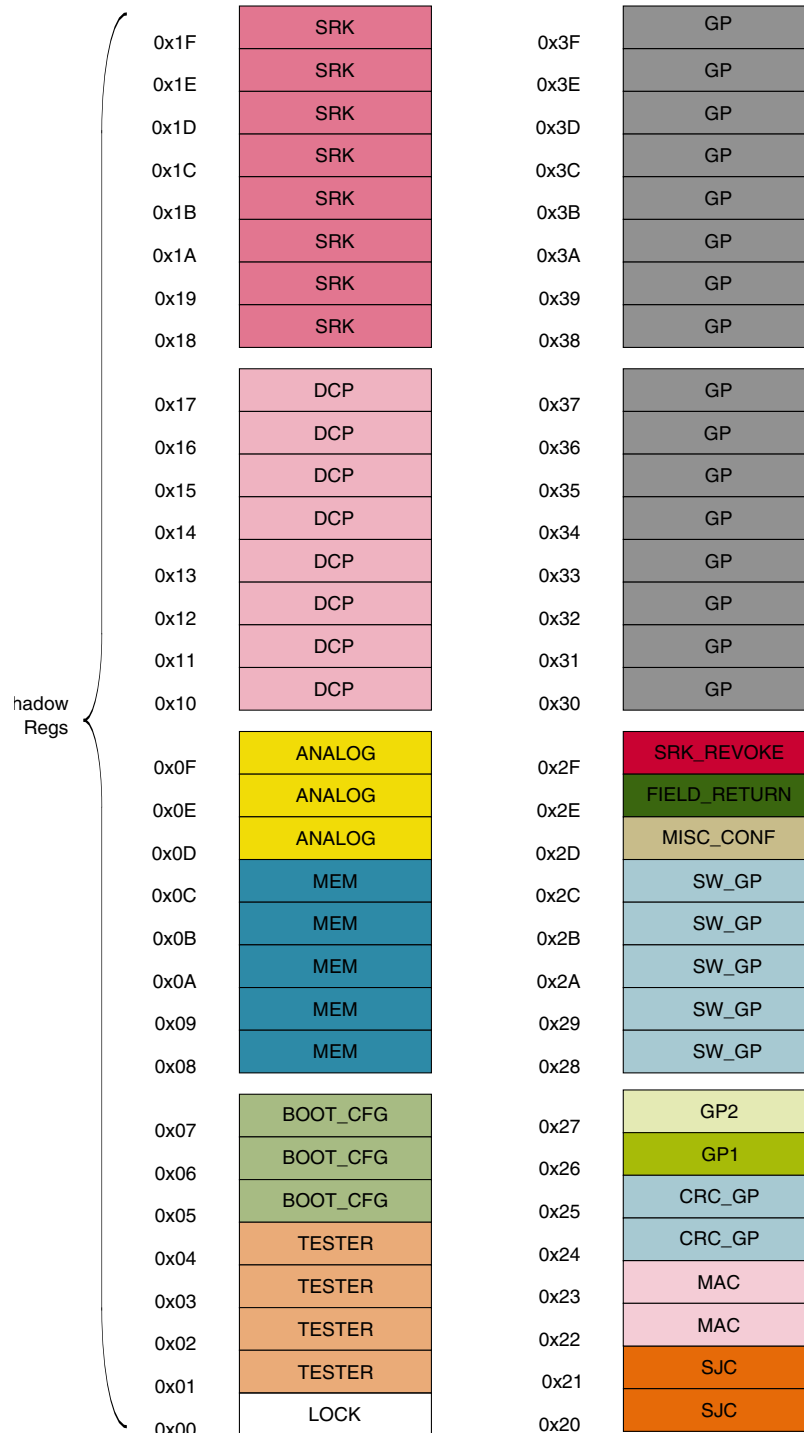

A recommended software sequence to meet the postamble requirements is as follows:

- Issue the write and poll for BUSY (as per [Fuse Shadow Memory Footprint](#)).
- Once BUSY is clear, use HW\_DIGCTL\_MICROSECONDS to wait 2 us.
- Perform the next OTP operation.

### 34.3.2 Fuse Shadow Memory Footprint

The OTP memory footprint is shown in the figure below. The registers are grouped by lock region. Their names correspond to the PIO register and fusemap names.

### 34.3.3 OTP Read/Write Timing Parameters

There are 3 timing fields contained in the HW\_OCOTP\_TIMING register that specify counter limit values, which are used to time how long the state machine remains in the various states, as well as specify the STROBE signal timing.

They are all specified in ipg\_clk cycles. Since the ipg\_clk frequency can be set to a range of values, these parameters must be adjusted with the clock to yield the appropriate delay.

The HW\_OCOTP\_TIMING[RELAX] field specifies how long to remain in states to meet setup and hold timing requirement in fuse spec. This parameter should be set by the following equation:

$$t_{RELAX} = t_{HP\_PG} = (HW\_OCOTP\_TIMING[RELAX]+1)/ipg\_frequency > 16.2ns$$

HW\_OCOTP\_TIMING[RELAX] field is used to create other setup and hold timing delays in addition to tHP\_PG. For all timing to be met, this is the max delay that must be programmed.

Except for setup and hold timing delay, there are 2 timing parameters for STROBE signal pulse width in program and read.

The HW\_OCOTP\_TIMING[STROBE\_PROG] field specifies the period of the STROBE signal for fuse writes and is given in units of ipg\_clk cycles. This value should be specified so that the requirement for the time when the STROBE signal is asserted high is met:  $9000ns < t_{PGM} < 11000ns$  is met. Even though a range is given for tPGM, it is advised in [eFUSE] to program for a value of 10000ns. Therefore, this field should be set according to the following equation:

$$t_{PGM} = ((HW\_OCOTP\_TIMING[STROBE\_PROG]+1) - 2*(HW\_OCOTP\_TIMING[RELAX]+1))/ipg\_frequency = 10000ns.$$

The HW\_OCOTP\_TIMING[STROBE\_READ] field specifies the period of the STROBE signal for fuse reads and is given in units of ipg\_clk cycles. This field should be set according to the following equation:

$$t_{RD} = ((HW\_OCOTP\_TIMING[STROBE\_READ]+1) - 2*(HW\_OCOTP\_TIMING[RELAX]+1))/ipg\_frequency > 36ns.$$

The figure below illustrates the relationship between the STROBE signal in programming and reading mode, as well as the timing PIO register fields that affect it. The implementation uses one counter to generate the STROBE waveform within one period and a second counter counts the number of cycles to create for programming the designated word.

**Figure 34-3. STROBE Signal Creation and Timing**

### 34.3.4 Hardware Visible Fuses

The `hwv_fuse` bus emanates from the OCOTP block and goes to various other blocks inside the chip. This bus is made up of the shadow register bits for banks 0, 1, 2 and 4.

Only a subset of these fuse bits are currently used by the hardware. The fuse bits are initially copied from the eFuse banks after reset is deasserted. When all fuse bits are loaded into their shadow registers, the OCOTP asserts the `fuse_latched` output signal.

The `hwv_reg` bus also comes from the OCOTP. Its source is the `HW_OCOTP_SCS` register. This register has 1 defined bit, the `HAB_JDE` bit, that is connected to the SJC block. The SCS bits are intended to be used as volatile fuse bits under software control. Additional bits will be defined as needed in future implementations.

The system-wide reset sequence must be coordinated by the system reset controller so that the `hwv_fuse` and `hwv_reg` busses are stable and reflect the values of the fuses before they are used by the rest of the system.

### 34.3.5 Behavior During Reset

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time `HW_OCOTP_CTRL_BUSY` is set. The load time is similar to that of a "reload shadow" operation.

### 34.3.6 Secure JTAG control

The JTAG control fuses are used to allow or disallow JTAG access to secured resources.

Three JTAG security levels are envisioned, as shown in the table below.

**Table 34-2. JTAG Security Level Control Bits**

Security Mode	JTAG_SMODE	Description
No Debug	2'b11	The highest security level.
Secure JTAG	2'b01	Limit the JTAG access by using key based authentication mechanism.
JTAG Enable	2'b00	Low Security, all JTAG features are enabled.

## 34.4 Fuse Map

See your Freescale representative for the fuse map (fuse bit definition).

## 34.5 OCOTP Memory Map/Register Definition

OCOTP Hardware Register Format Summary

**OCOTP memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
21B_C000	OTP Controller Control Register (OCOTP_CTRL)	32	R/W	0000_0000h	<a href="#">34.5.1/2188</a>
21B_C004	OTP Controller Control Register (OCOTP_CTRL_SET)	32	R/W	0000_0000h	<a href="#">34.5.1/2188</a>
21B_C008	OTP Controller Control Register (OCOTP_CTRL_CLR)	32	R/W	0000_0000h	<a href="#">34.5.1/2188</a>

### 34.5.1 OTP Controller Control Register (OCOTP\_CTRLn)

The OCOTP Control and Status Register specifies the copy state, as well as the control required for random access of the OTP memory

OCOTP\_CTRL: 0x000

OCOTP\_CTRL\_SET: 0x004

OCOTP\_CTRL\_CLR: 0x008

OCOTP\_CTRL\_TOG: 0x00C

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP (One-Time Programmable ROM). The control fields such as WR\_UNLOCK, ADDR and BUSY/ERROR may be used in conjunction with the OCOTP\_DATA register to perform write operations. Read operations to the On-Chip OTP are involving ADDR, BUSY/ERROR bit field and OCOTP\_READ\_CTRL register. Read value is saved in OCOTP\_READ\_FUSE\_DATA register.

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 0h offset + (4d × i), where i=0d to 3d

OCOTP\_CTRLn field descriptions

Field	Description
31–16 WR_UNLOCK	Write 0x3E77 to enable OTP write accesses. NOTE: This register must be unlocked on a write-by-write basis (a write is initiated when HW_OCOTP_DATA is written), so the UNLOCK bitfield must contain the correct key value during all writes to HW_OCOTP_DATA, otherwise a write shall not be initiated. This field is automatically cleared after a successful write completion (clearing of BUSY).  0x3E77 <b>KEY</b> — Key needed to unlock HW_OCOTP_DATA register.
15–13 RSVD1	Reserved
12 CRC_FAIL	Set by controller when calculated CRC value is not equal to appointed CRC fuse word
11 CRC_TEST	Set to calculate CRC according to start address and end address in CRC_ADDR register. And compare with CRC fuse word according CRC address in CRC_ADDR register to generate CRC_FAIL flag
10 RELOAD_SHADOWS	Set to force re-loading the shadow registers (HW/SW capability and LOCK). This operation will automatically set BUSY. Once the shadow registers have been re-loaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller.
9 ERROR	Set by the controller when an access to a locked region(OTP or shadow register) is requested. Must be cleared before any further access can be performed. This bit can only be set by the controller. This bit is also set if the Pin interface is active and software requests an access to the OTP. In this instance, the ERROR bit cannot be cleared until the Pin interface access has completed. Reset this bit by writing a one to the SCT clear address space and not by a general write.
8 BUSY	OTP controller status bit. When active, no new write access or read access to OTP(including RELOAD_SHADOWS) can be performed. Cleared by controller when access complete. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the HW/SW and LOCK registers are successfully copied, after which time it is automatically cleared by the controller.
7–6 RSVD0	Reserved
5–0 ADDR	OTP write and read access address register. Specifies one of 64 word address locations (0x00 - 0x3f). If a valid access is accepted by the controller, the controller makes an internal copy of this value. This internal copy will not update until the access is complete.

### 34.5.2 OTP Controller Timing Register (OCOTP\_TIMING)

The OCOTP Data Register is used for OTP Programming

This register specifies timing parameters for programming and reading the OCOTP fuse array.

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 10h offset = 21B\_C010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSRVD0				WAIT				STROBE_READ				RELAX				STROBE_PROG															
W																																
Reset	0	0	0	0	0	0	0	1	0	1	0	0	0	1	1	0	0	0	0	1	0	0	1	0	1	0	0	1	1	0	0	1

#### OCOTP\_TIMING field descriptions

Field	Description
31–28 RSRVD0	These bits always read back zero.
27–22 WAIT	This count value specifies time interval between auto read and write access in one time program. It is given in number of ipg_clk periods.
21–16 STROBE_READ	This count value specifies the strobe period in one time read OTP. $Trd = ((STROBE\_READ+1) - 2*(RELAX+1)) / ipg\_clk\_freq$ . It is given in number of ipg_clk periods.
15–12 RELAX	This count value specifies the time to add to all default timing parameters other than the Tpgm and Trd. It is given in number of ipg_clk periods.
11–0 STROBE_PROG	This count value specifies the strobe period in one time write OTP. $Tpgm = ((STROBE\_PROG+1) - 2*(RELAX+1)) / ipg\_clk\_freq$ . It is given in number of ipg_clk periods.

### 34.5.3 OTP Controller Write Data Register (OCOTP\_DATA)

The OCOTP Data Register is used for OTP Programming

This register is used in conjunction with OCOTP\_CTRL to perform one-time writes to the OTP. Please see the "Software Write Sequence" section for operating details.

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 20h offset = 21B\_C020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DATA																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

### OCOTP\_DATA field descriptions

Field	Description
31–0 DATA	Used to initiate a write to OTP. Please see the "Software Write Sequence" section for operating details.

## 34.5.4 OTP Controller Write Data Register (OCOTP\_READ\_CTRL)

The OCOTP Register is used for OTP Read

This register is used in conjunction with OCOTP\_CTRL to perform one time read to the OTP. Please see the "Software read Sequence" section for operating details.

### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 30h offset = 21B\_C030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0															READ_FUSE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**OCOTP\_READ\_CTRL field descriptions**

Field	Description
31–1 RSVD0	Reserved
0 READ_FUSE	Used to initiate a read to OTP. Please see the "Software read Sequence" section for operating details.

### 34.5.5 OTP Controller Read Data Register (OCOTP\_READ\_FUSE\_DATA)

The OCOTP Data Register is used for OTP Read

The data read from OTP

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 40h offset = 21B\_C040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**OCOTP\_READ\_FUSE\_DATA field descriptions**

Field	Description
31–0 DATA	The data read from OTP

### 34.5.6 Sticky bit Register (OCOTP\_SW\_STICKY)

Some SW sticky bits .

Some sticky bits are used by SW to lock some fuse area, shadow registers and other features.

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 50h offset = 21B\_C050h

**OCOTP\_SW\_STICKY field descriptions**

Field	Description
31–5 RSVD0	Reserved
4–3 -	Reserved
2 FIELD_RETURN_LOCK	Shadow register write and OTP write lock for FIELD_RETURN region. When set, the writing of this region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.
1 SRK_REVOKE_LOCK	Shadow register write and OTP write lock for SRK_REVOKE region. When set, the writing of this region's shadow register and OTP fuse word are blocked. Once this bit is set, it is always high unless a POR is issued.
0 -	Reserved

### 34.5.7 Software Controllable Signals Register (OCOTP\_SCSn)

OCOTP\_SCS: 0x060

OCOTP\_SCS\_SET: 0x064

OCOTP\_SCS\_CLR: 0x068

OCOTP\_SCS\_TOG: 0x06C

This register holds volatile configuration values that can be set and locked by trusted software. All values are returned to their default values after POR.

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 60h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	LOCK	SPARE														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SPARE															HAB_JDE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### OCOTP\_SCSn field descriptions

Field	Description
31 LOCK	When set, all of the bits in this register are locked and can not be changed through SW programming. This bit is only reset after a POR is issued.
30–1 SPARE	Unallocated read/write bits for implementation specific software use.
0 HAB_JDE	<p>HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properlay signed command to do so is found and validated by the HAB.</p> <p>The HAB must lock the register before passing control to the OS whether or not JTAG debugging has been enabled.</p> <p>Once JTAG is enabled by this bit, it can not be disabled unless the system is reset by POR. 0: JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms).</p> <p>1: JTAG debugging is enabled by the HAB (though this signal may be gated off).</p>

### 34.5.8 OTP Controller CRC test address (OCOTP\_CRC\_ADDR)

The OCOTP Data Register is used for OTP Read

The address for CRC calculation

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 70h offset = 21B\_C070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0													CRC_ADDR			DATA_END_ADDR								DATA_START_ADDR							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**OCOTP\_CRC\_ADDR field descriptions**

Field	Description
31–19 RSVD0	Reserved
18–16 CRC_ADDR	Address of 32-bit CRC result for comparing
15–8 DATA_END_ADDR	Start address of fuse location for CRC calculation
7–0 DATA_START_ADDR	End address of fuse location for CRC calculation

### 34.5.9 OTP Controller CRC Value Register (OCOTP\_CRC\_VALUE)

The OCOTP Data Register is used for OTP Read

The crc32 value based on CRC\_ADDR

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 80h offset = 21B\_C080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DATA																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**OCOTP\_CRC\_VALUE field descriptions**

Field	Description
31–0 DATA	The crc32 value based on CRC_ADDR

**34.5.10 OTP Controller Timing Register (OCOTP\_UMC\_TIMING)**

The OCOTP Data Register is used for OTP Programming

This register specifies timing parameters for programming UMC OCOTP fuse array.

**EXAMPLE**

Empty Example.

Address: 21B\_C000h base + 90h offset = 21B\_C090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSRVD0																STROBE_PROG_INT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	1	0

**OCOTP\_UMC\_TIMING field descriptions**

Field	Description
31–12 RSRVD0	These bits always read back zero.
11–0 STROBE_PROG_INT	This count value specifies the strobe pulse interval in one time write OTP. $T_{pi} = (STROBE\_PROG + 1) / ipg\_clk\_freq$ . It is given in number of ipg_clk periods.

**34.5.11 OTP Controller Version Register (OCOTP\_VERSION)**

This register always returns a known read value for debug purposes it indicates the version of the block.

This register indicates the RTL version in use.

**EXAMPLE**

Empty Example.

Address: 21B\_C000h base + A0h offset = 21B\_C0A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	MAJOR								MINOR								STEP															
W																																
Reset	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### OCOTP\_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
15–0 STEP	Fixed read-only value reflecting the stepping of the RTL version.

## 34.5.12 Value of OTP Bank0 Word0 (Lock controls) (OCOTP\_LOCK)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS]

Shadowed memory mapped access to OTP Bank 0, word 0 (ADDR = 0x00).

### EXAMPLE

Empty Example.

## OCOTP Memory Map/Register Definition

Address: 21B\_C000h base + 400h offset = 21B\_C400h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	UNALLOCATED		GP_HI_LOCK		GP_LO_LOCK		PIN	RSVD2	-	MISC_CONF	CRC_GP_LOCK		ANALOG		DCP	SW_GP
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD1	SRK	GP2		GP1		MAC_ADDR		RSVD0	SJC_RESP	MEM_TRIM		BOOT_CFG		TESTER	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### OCOTP\_LOCK field descriptions

Field	Description
31–30 UNALLOCATED	Value of un-used portion of LOCK word
29–28 GP_HI_LOCK	Status of shadow register and OTP write lock for GP region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
27–26 GP_LO_LOCK	Status of shadow register and OTP write lock for GP region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

Table continues on the next page...

**OCOTP\_LOCK field descriptions (continued)**

<b>Field</b>	<b>Description</b>
25 PIN	Status of Pin access lock bit. When set, pin access is disabled.
24 RSVD2	Reserved
23 -	Reserved
22 MISC_CONF	Status of shadow register and OTP write lock for misc_conf region. When set, the writing of this region's shadow register and OTP fuse word are blocked.
21–20 CRC_GP_LOCK	Status of shadow register write and read, OTP program and read lock for CRC region. When bit 1 is set, the reading and writing of this region's OTP fuse and reading of shadow register are blocked. When bit 0 is set, the writing of this region's shadow register and OTP fuse are blocked.
19–18 ANALOG	Status of shadow register and OTP write lock for analog region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
17 DCP	Status of shadow register read and write, OTP read and write lock for otpmk region. When set, the writing of this region's shadow register and OTP fuse word are blocked. The read of this region's shadow register and OTP fuse word are also blocked.
16 SW_GP	Status of shadow register lock for the region contained in the SW_GP registers. When set, the over-riding (writing) of this region's shadow bits is blocked. These shadow registers are always readable.
15 RSVD1	Reserved
14 SRK	Status of shadow register and OTP write lock for srk region. When set, the writing of this region's shadow register and OTP fuse word are blocked.
13–12 GP2	Status of shadow register and OTP write lock for gp2 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
11–10 GP1	Status of shadow register and OTP write lock for gp2 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
9–8 MAC_ADDR	Status of shadow register and OTP write lock for mac_addr region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
7 RSVD0	Reserved
6 SJC_RESP	Status of shadow register read and write, OTP read and write lock for sjc_resp region. When set, the writing of this region's shadow register and OTP fuse word are blocked. The read of this region's shadow register and OTP fuse word are also blocked.
5–4 MEM_TRIM	Status of shadow register and OTP write lock for mem_trim region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
3–2 BOOT_CFG	Status of shadow register and OTP write lock for boot_cfg region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.
1–0 TESTER	Status of shadow register and OTP write lock for tester region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

### 34.5.13 Value of OTP Bank0 Word1 (Configuration and Manufacturing Info.) (OCOTP\_CFG0)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS]

Shadowed memory mapped access to OTP Bank 0, word 1 (ADDR = 0x01).

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 410h offset = 21B\_C410h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### OCOTP\_CFG0 field descriptions

Field	Description
31–0 BITS	This register contains 32 bits of the Unique ID and SJC_CHALLENGE field. Reflects value of OTP Bank 0, word 1 (ADDR = 0x01). These bits become read-only after the HW_OCOTP_LOCK_TESTER[1] bit is set.

### 34.5.14 Value of OTP Bank0 Word2 (Configuration and Manufacturing Info.) (OCOTP\_CFG1)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS]

shadowed memory mapped access to OTP Bank 0, word 2 (ADDR = 0x02).

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 420h offset = 21B\_C420h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### OCOTP\_CFG1 field descriptions

Field	Description
31–0 BITS	This register contains 32 bits of the Unique ID and SJC_CHALLENGE field. Reflects value of OTP Bank 0, word 2 (ADDR = 0x02). These bits become read-only after the HW_OCOTP_LOCK_TESTER[1] bit is set.

### 34.5.15 Value of OTP Bank0 Word3 (Configuration and Manufacturing Info.) (OCOTP\_CFG2)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS]

Shadowed memory mapped access to OTP Bank 0, word 3 (ADDR = 0x03).

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 430h offset = 21B\_C430h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### OCOTP\_MEM0 field descriptions

Field	Description
31–0 BITS	Reflects value of OTP bank 1, word 0 (ADDR = 0x08). These bits become read-only after the HW_OCOTP_LOCK_MEM_TRIM[1] bit is set.

### 34.5.21 Value of OTP Bank1 Word1 (Memory Related Info.) (OCOTP\_MEM1)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS]

Shadowed memory mapped access to OTP bank 1, word 1 (ADDR = 0x09).

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 490h offset = 21B\_C490h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### OCOTP\_SRK5 field descriptions

Field	Description
31–0 BITS	Shadow register for the hash of the Super Root Key word5 (Copy of OTP Bank 3, word 5 (ADDR = 0x21)). These bits become read-only after the HW_OCOTP_LOCK_SRK bit is set.

## 34.5.42 Shadow Register for OTP Bank3 Word6 (SRK Hash) (OCOTP\_SRK6)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS].

Shadowed memory mapped access to OTP Bank 3, word 6 (ADDR = 0x1E).

### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 5E0h offset = 21B\_C5E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	<div>BITS</div>

#### OCOTP\_SRK6 field descriptions

Field	Description
31–0 BITS	Shadow register for the hash of the Super Root Key word6 (Copy of OTP Bank 3, word 6 (ADDR = 0x22)). These bits become read-only after the HW_OCOTP_LOCK_SRK bit is set.

### 34.5.43 Shadow Register for OTP Bank3 Word7 (SRK Hash) (OCOTP\_SRK7)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS].

Shadowed memory mapped access to OTP Bank 3, word 7 (ADDR = 0x1F).

### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 5F0h offset = 21B\_C5F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### OCOTP\_SRK7 field descriptions

Field	Description
31–0 BITS	Shadow register for the hash of the Super Root Key word7 (Copy of OTP Bank 3, word 7 (ADDR = 0x23)). These bits become read-only after the HW_OCOTP_LOCK_SRK bit is set.

### 34.5.44 Value of OTP Bank4 Word0 (Secure JTAG Response Field) (OCOTP\_SJC\_RESP0)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS]

Shadowed memory mapped access to OTP Bank 4, word 0 (ADDR = 0x20).

## EXAMPLE

Empty Example.

Address: 21B\_C000h base + 600h offset = 21B\_C600h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### OCOTP\_SJC\_RESP0 field descriptions

Field	Description
31–0 BITS	Shadow register for the SJC_RESP Key word0 (Copy of OTP Bank 4, word 0 (ADDR = 0x20)). These bits can be not read and wrotten after the HW_OCOTP_LOCK_SJC_RESP bit is set. If read, returns 0xBADA_BADA and sets HW_OCOTP_CTRL[ERROR].

## 34.5.45 Value of OTP Bank4 Word1 (Secure JTAG Response Field) (OCOTP\_SJC\_RESP1)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS]

Shadowed memory mapped access to OTP Bank 4, word 1 (ADDR = 0x21).

## EXAMPLE

Empty Example.

Address: 21B\_C000h base + 610h offset = 21B\_C610h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### OCOTP\_SJC\_RESP1 field descriptions

Field	Description
31–0 BITS	Shadow register for the SJC_RESP Key word1 (Copy of OTP Bank 4, word 1 (ADDR = 0x21)). These bits can be not read and wrotten after the HW_OCOTP_LOCK_SJC_RESP bit is set. If read, returns 0xBADA_BADA and sets HW_OCOTP_CTRL[ERROR].

### 34.5.46 Value of OTP Bank4 Word2 (MAC Address) (OCOTP\_MAC0)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP\_CTRL[RELOAD\_SHADOWS]

Shadowed memory mapped access to OTP Bank 4, word 2 (ADDR = 0x22).

#### EXAMPLE

Empty Example.

Address: 21B\_C000h base + 620h offset = 21B\_C620h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## Chapter 35

# On-Chip RAM Memory Controller (OCRAM)

### 35.1 Overview

There are 2 OCRAM controllers implemented in i.MX 6SoloLite. One controller is for the normal 128KB on-chip RAM. The other controller is for the 256KB L2 cache of ARM platform.

The L2 cache can be configured into "OCRAM mode" and used in the same way as normal OCRAM. The on-chip RAM block is implemented as a slave module on the 64-bit system AXI bus. Designed as a simple on-chip memory controller, it supports only one AXI port with memory banks. For the AXI port, the read and write transactions are handled by two independent modules. As it is possible to have simultaneous read and write request from the AXI bus, each memory bank has an arbiter with round-robin scheme. After arbitration, the granted read or write access command can then be issued to the memory cell through a read/write MUX.

The 4 memory banks are organized with lower 2 bits of address which is AXI bus address and is 64 bits aligned interleaved. This allows a read access and a write access can be processed at the same time if they are targeted to different memory banks.

Various options are provided for adding pipeline or wait-states in read/write access, in order to ensure flexible timing control at both high and low frequencies.

The internal block diagram is shown in the figure below.

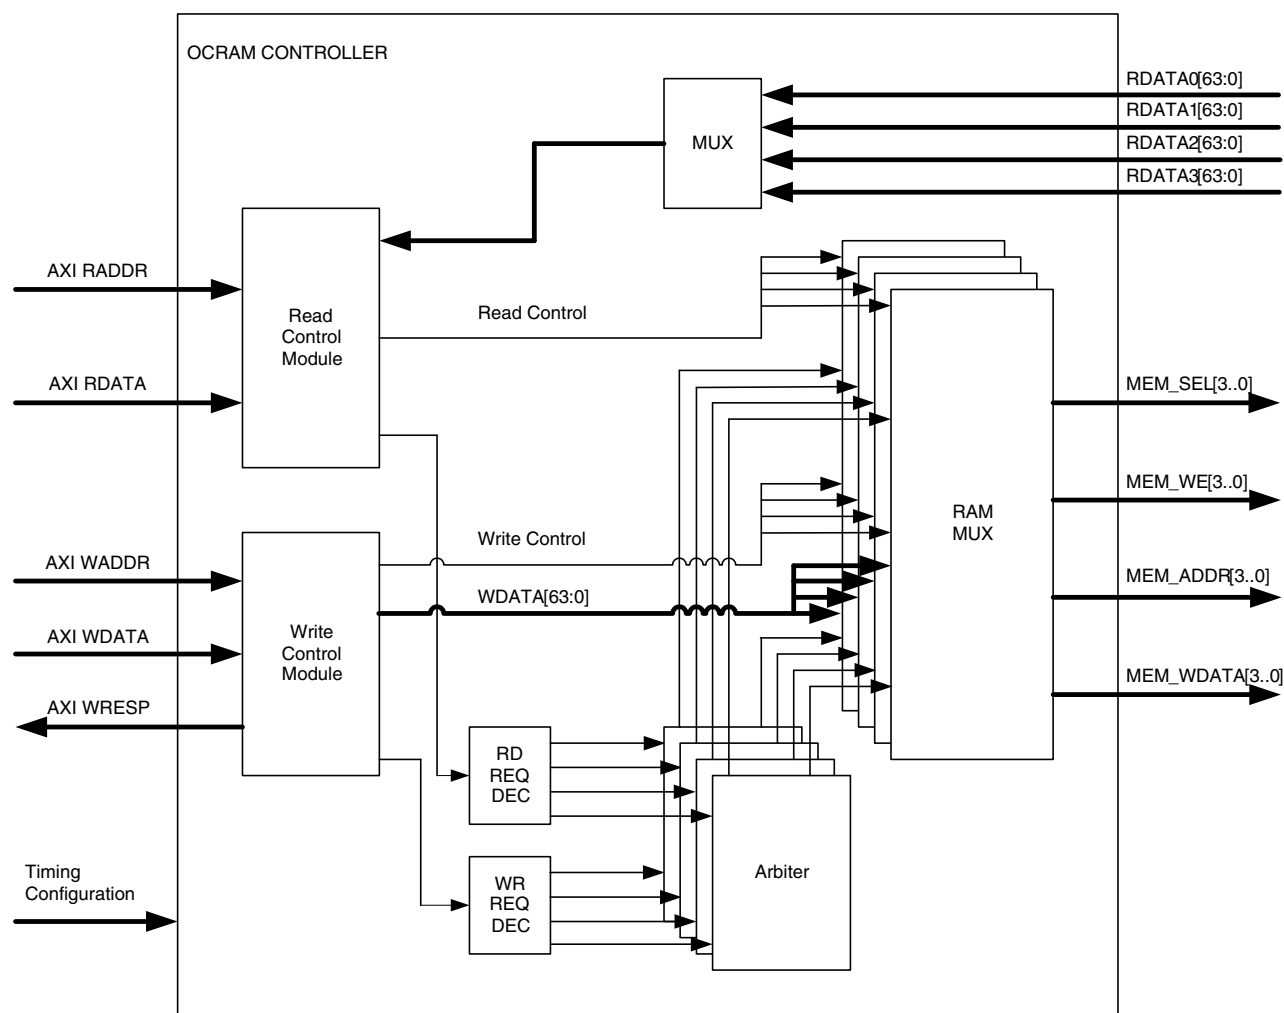

Figure 35-1. On-chip RAM Block Diagram

## 35.2 Basic Functions

### 35.2.1 Read/Write Arbitration

The arbiter is used to handle the read/write request from the read control module and write control module. It grants read/write access to the memory cell according to the internal arbitration state and the request/switch signal from the read control module and write control module. Generally, the arbitration is using the round-robin method.

The detailed rules used in arbitration are as follows:

- If there is no granted read or write in the last cycle, and there is only a read request or a write request, the request will be granted.
- If there is no granted read or write in the last cycle, and there are both read or write requests coming in at the same time, the read request will be granted first.
- If a granted read/write transaction has just finished, the write/read request will have the higher priority in the next cycle.
- If the first read/write access request in a transaction is granted, all the data transfer in this burst will be finished before the next arbitration begins, that is, the round-robin arbitration mechanism is based on AXI transaction, not data access.

### 35.2.2 TrustZone

TrustZone is also supported on this block.

When SECURE\_ENBL bit in the General Purpose Register (IOMUXC\_GPR10) bits [10:4] and [26:20] is set, the STARTADDR and ENDADDR bit-fields in this register establish the region of OCRAM that can only be accessed (both read and write) according to the execution mode policy described in CSU chapter, [Peripheral access policy](#). If this bit is cleared to zero, the entire OCRAM can be accessed in either secure or non-secure mode. The TrustZone bits shows in [Programmable Registers](#).

#### NOTE

The ENDADDR is not configurable and its value is the last address of the OCRAM space. The STARTADDR granularity is of 4KB.

## 35.3 Advanced Features

This section describes some advanced features designed to avoid timing issues when the on-chip RAM is working at high frequency.

All of the features can be disabled/enabled by programming the corresponding fields of the General Purpose Register (IOMUXC.GPR3) bits [24:21] and bits [3:0] in the IOMUX chapter.

### 35.3.1 Read Data Wait State

When the wait state is enabled, it will cost 2 cycles for each read access, (each beat of a read burst).

This can avoid the potential timing problem caused by the relatively longer memory access time at higher frequency.

When this feature is disabled, it only costs 1 clock cycle to finish a read transaction, that is, to get read data back in the next cycle of read request becomes valid on the bus.

For the normal ocram, the read data wait state is configurable via IOMUXC.GPR3[21]. For the L2 cache as ocram, the read data wait state is configurable via IOMUXC.GPR3[0].

### **35.3.2 Read Address Pipeline**

When this feature is enabled, the read address from the AXI master is delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issues for the read access on the memory cell at high frequency. Enabling this feature can cost, at most, 1 more clock cycle for each AXI read transaction, that is, at most 1 more clock cycle for each read burst with multiple beats of data.

When this feature is disabled, the read address from the AXI master can be accepted by the on-chip RAM without delay, and data can become ready for master at next clock cycle (if no other access and no read data wait).

For the normal ocram, the read address pipeline is configurable via IOMUXC.GPR3[22]. For the L2 cache as ocram, the read address pipeline is configurable via IOMUXC.GPR3[1].

### **35.3.3 Write Data Pipeline**

When this feature is enabled, the write data from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write data from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

For the normal ocram, the write data pipeline is configurable via IOMUXC.GPR3[23].  
For the L2 cache as ocram, the write data pipeline is configurable via IOMUXC.GPR3[2].

### 35.3.4 Write Address Pipeline

When this feature is enabled, the write address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write address from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle).

For the normal ocram, the write address pipeline is configurable via IOMUXC.GPR3[24].  
For the L2 cache as ocram, the write address pipeline is configurable via IOMUXC.GPR3[3]

## 35.4 Programmable Registers

There are no programmable registers in this block; however, OCRAM configurable bits can be found in the IOMUX Controller (IOMUXC) general purpose registers found here.

- TrustZone bits: IOMUXC\_GPR10
- WAIT state / Pipeline bits: IOMUXC\_GPR3
- L2 Cache OCRAM enable bits: IOMUXC\_GPR11

(See [IOMUXC Memory Map/Register Definition](#) for more details).

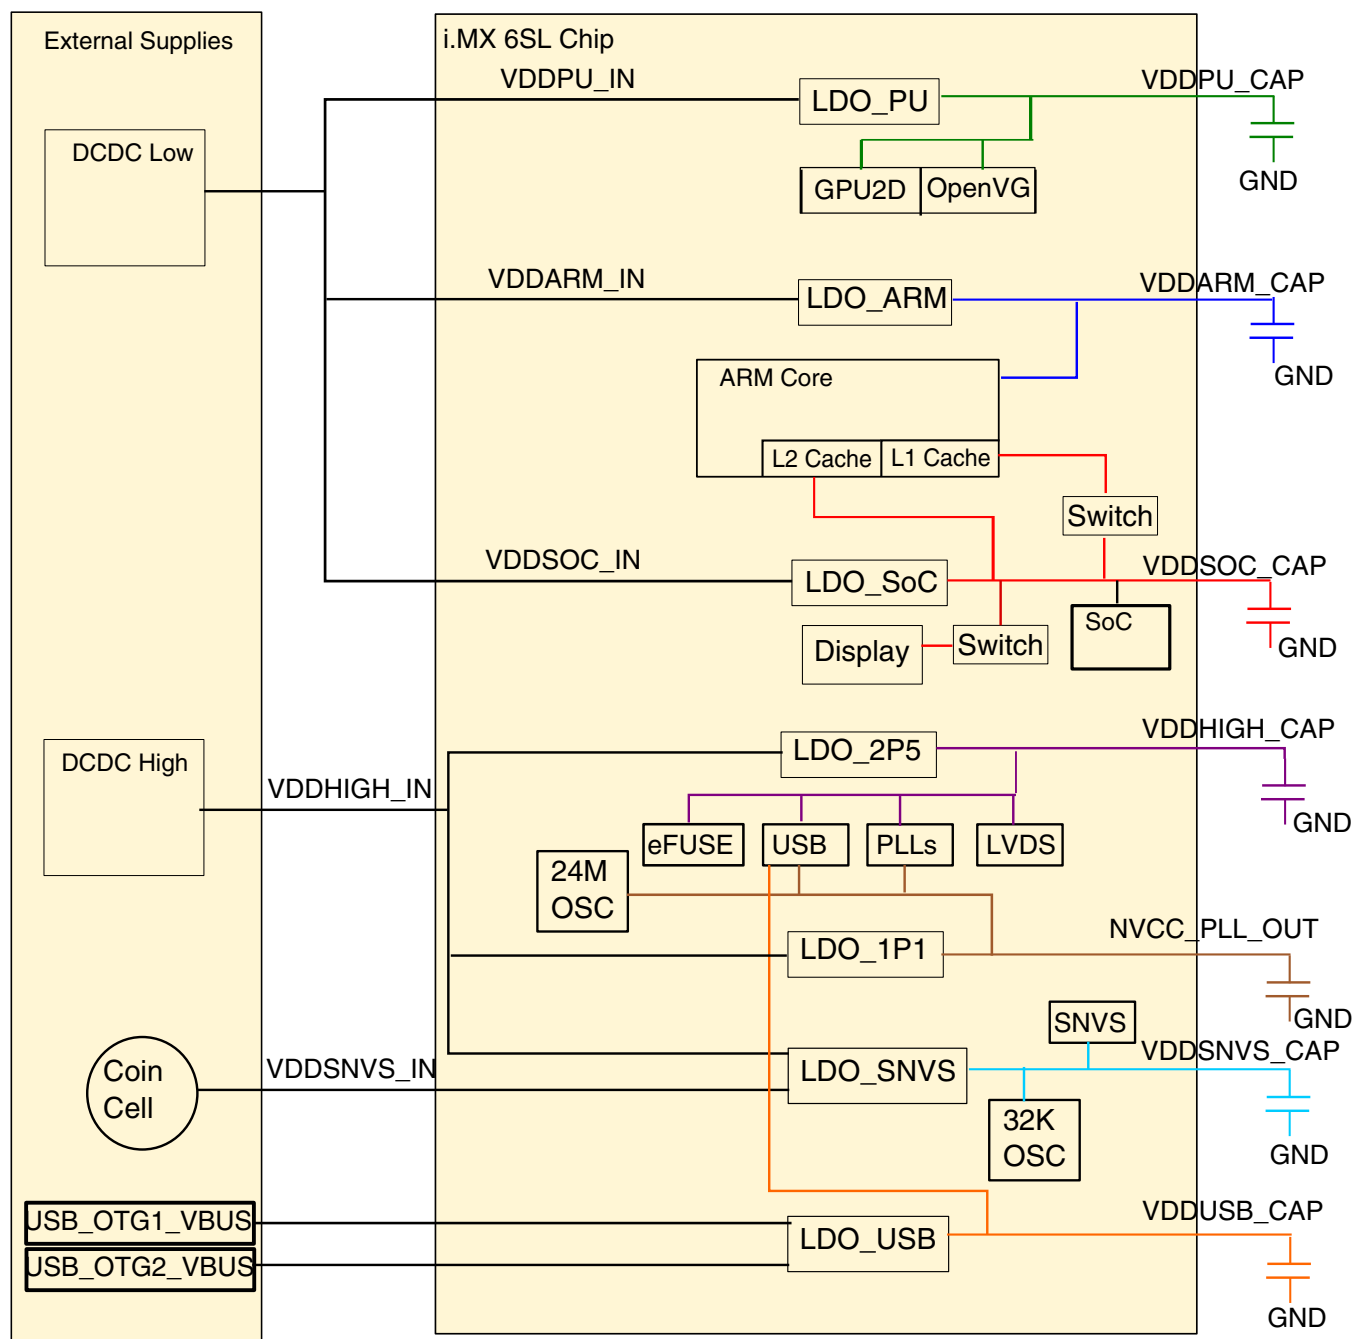

## **Chapter 36**

# **Power Management Unit (PMU)**

### **36.1 Overview**

The power management unit (PMU) is designed to simplify the external power interface. The power system can be split into the input power sources and their characteristics, the integrated power transforming and controlling elements, and the final load interconnection and requirements.

A typical power system utilizing the PMU is depicted below.

**Figure 36-1. Power system overview**

Utilizing seven LDO regulators, the number of external supplies is greatly reduced. Not counting the backup coin and USB inputs, the number of external supplies is reduced to two. Missing from this external supply total is the number of necessary external supplies to power the desired memory interface; that number varies depending on the type of

external memory selected. Other supplies may also be necessary to supply the voltage to the different I/O power segments if their I/O voltages have to be different from what is provided above.

## 36.2 Digital LDO Regulators

The PMU has three digital LDO regulators. They are referred to as "digital" because of the logic loads they drive, not because of their construction. These regulators have three basic modes that are unique to the digital regulators.

- **Internal Bypass**—The regulation FET is switched fully on passing the external input voltage to the load unaltered. The analog part of the regulator is powered down in this state, removing any loss other than the IR drop through the power grid and the FET. (TARG = 0x1F)
- **External Bypass**—The input and output of the regulator are shorted externally to the part. If operating in this configuration, enable the internal bypass early in the start-up sequence before attempting high-frequency/high-power operation.
- **Power Gate**—The regulation FET is switched off fully, limiting the current draw from the supply. The analog part of the regulator is powered down, limiting the power consumption. The output voltage falls to a level at which the residual leakage of the power FET balances with the leakage of the load. (TARG = 0x00)
- **Analog regulation mode**—The regulation FET is controlled such that the output voltage of the regulator equals the programmed target voltage. The target voltage is fully programmable in 25-mV steps.

These modes allow the regulators to implement voltage scaling and power gating and allow bypass. With the bypass feature, all of the accuracy and control requirements can be shifted to the external supply source if capable and desired.

These digital regulators also feature brownout detection which is helpful when supplies are starting to collapse. The voltage value where brownout is signaled is programmable as an offset from the programmed target voltage. The controls are located in the PMU\_MISC2 register. The core is interrupted on a brownout.

The three digital regulators are known as LDO\_ARM (#0), LDO\_PU (#1), and LDO\_SOC (#2). As shown in the power system overview figure, the ARM regulator powers the ARM cores. The PU powers the GPU and display portions of the chip. The SOC regulator powers the rest of the digital logic on the chip. The target voltages of these regulators are all reset to 1.1 V on startup. All regulators support generous programming ranges in 25-mV steps. It is possible to program voltages above the process limit for the

chip, thus causing permanent damage. Likewise, it is possible to program the voltage so low that the chip cannot continue to operate or even retain state without clocks. Care should be taken with these settings.

Care must be taken when raising the output voltage of the regulator rapidly. This can cause large currents to flow into the output cap of the regulator up to the limits of the input supply. When the input supply capability is exceeded, this can cause an input supply dip that may affect other regulators on the same supply. Therefore, the rate of voltage change on the output of the regulator should be limited. When powering up the regulator, the integrated current limiter controls the ramp rate. This limiter is only effective when transitioning from the off state of the regulator (bypassed or power gated). However, in a DVFS situation, the same high rate of change can occur if the target voltage is raised rapidly by software. To limit the rate of change, the hardware controlling the regulator effects a piecewise linear ramp by stepping the output voltage in 25-mV steps until the desired output voltage is reached. The slope of the ramp is controlled by the time spent at each 25-mV step and is controlled by the step time field in the PMU\_MISC2 register. The same situation is not a problem when the output voltage is dropped as the load pulls down the output cap. As a result, any reduction in the programmed regulator target voltage is immediately effective with the actual supply voltage falling at a rate controlled by the load on the regulator.

## 36.3 Analog LDO Regulators

There are two analog regulators described here.

### 36.3.1 LDO 1P1

The LDO\_1P1 module on the chip implements a programmable linear-regulator function from a higher analog supply voltage (2.8 V–3.3 V) to produce a nominal 1.1-V output voltage.

The output of the regulator can be programmed in 25-mV steps from 0.8 V to 1.4 V and can provide up to 150 mA output current. The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitor of 2.2  $\mu$ F, though the actual capacitance required should be determined by the application. A programmable brownout detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded, so the necessary steps can be taken. Current limiting can be enabled by setting the PMU\_REG\_1P1[ENABLE\_ILIMIT] bit to

allow for in-rush current requirements during startup if needed. Active pulldown can also be enabled by setting the PMU\_REG\_1P1[ENABLE\_PULLDOWN] bit for systems requiring this feature.

### 36.3.2 LDO 2P5

The LDO\_2P5 module on the chip implements a programmable linear-regulator function from a higher analog supply voltage (2.8V-3.3V) to produce a nominal 2.5V output voltage.

The output of the regulator can be programmed in 25mV steps from 2.0V to 2.75V and can provide up to 350mA output current with a 300mV drop-out voltage. The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitor of 2.2 $\mu$ F, though the actual capacitance required should be determined by the application. A programmable brown-out detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded to take the necessary steps. Current-limiting can be enabled by setting the REG\_PMU\_2P5[ENABLE\_ILIMIT] bit to allow for in-rush current requirements during start-up if needed. Active-pulldown can also be enabled by setting the REG\_PMU\_2P5[ENABLE\_PULLDOWN] bit for systems requiring this feature.

#### 36.3.2.1 Low Power Operation

The 2.5 V LDO includes an alternate, self-biased, low-precision, weak regulator which can be enabled for applications needing to keep the 2.5-V output voltage alive during low-power modes where the main regulator and its associated global bandgap reference module are disabled. The output of this weak regulator is not programmable and is a function of its input power supply as well as load current. Typically, with a 3-V input power supply, the weak regulator output is 2.525 V, and its output impedance is approximately 40  $\Omega$ .

The low-power mode is enabled by setting high the PMU\_REG\_2P5[ENABLE\_WEAK\_LINREG] bit of the regulator. It is recommended that the following sequence be followed to enable this mode:

1. Throttle down the 2.5-V attached load to its low-power maintain state.
2. Disable the main 2.5-V regulator driver by clearing the PMU\_REG\_2P5[ENABLE\_LINREG] bit.
3. Enable the weak 2.5-V regulator by setting the PMU\_REG\_2P5[ENABLE\_WEAK\_LINREG] bit.

To go back to full-power operation, reverse the steps outlined above. Note that the external decoupling cap is supporting the power supply between steps 2 and 3. Therefore step 3 should happen appropriately in time relative to the discharge of the supporting capacitor.

## 36.4 USB LDO Regulator

The USB\_LDO module on the chip implements a programmable linear-regulator function from the USB VBUS voltages (typically 5 V) to produce a nominal 3.0-V output voltage.

The output of the regulator can be programmed in 25-mV steps, from 2.625V to 3.4 V, and can provide up to 50mA output current. The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitor of 2.2  $\mu$ F, though the actual capacitance required should be determined by the application. A programmable brownout detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded, so the necessary steps can be taken. This regulator has a built-in power mux which allows the user to choose to run the regulator from either VBUS supply when both are present. If only one of the VBUS voltages is present, then the regulator automatically selects this supply. Current limit is also included to help the system meet in-rush current targets.

Upon attachment of VBUS, this regulator starts up in a low-power, self-preservation mode to prevent over-voltage conditions on the chip. It is expected that the user transition to full regulation by enabling the regulator and disabling the in-rush current limits via its control registers. Upon VBUS removal, it is further expected that the regulator controls are returned to their reset state.

## 36.5 SNVS Regulator

The SNVS regulator takes the SNVS\_IN supply and generates the SNVS\_CAP supply, which powers the real time clock and SNVS blocks.

If VDDHIGH\_IN is present, then the SNVS\_IN supply is internally shorted to the VDDHIGH\_IN supply to allow coin cell recharging if necessary. The output voltage is regulated to a 1.1V level.

VDDHIGH\_IN can be separated from SNVS\_IN by setting the `discon_high_snvs` bit in the `PMU_misc0`.

## 36.6 Power Modes

### 36.6.1 Reverse Well Biasing

The reverse well biasing module on the chip includes a self-clocked/self-regulating charge-pump circuit to generate a negative bias voltage for the floating PWELL, and a low-power regulator to generate a positive bias voltage for the NWELL of digital logic cells on the SOC power domain.

Static leakage reduction can be achieved through the use of these reverse well bias voltages. Typical power consumption of the module is 50  $\mu$ A when driving a 10-nF purely capacitive load.

## 36.7 PMU Memory Map/Register Definition

The register definitions that affect the behavior of the digital LDO regulators follow.

### NOTE

Some of the registers are collections of bits that affect multiple components on the chip. Those that are not pertinent to this chapter have comments in the related register bitfields.

If a full description is desired, please consult the full register programming reference in the related block.

### PMU\_REG\_CORE field descriptions

Field	Description
31–30 -	This field is reserved.
29 FET_ODRIVE	If set, increases the gate drive on power gating FETs to reduce leakage in the off state. Care must be taken to apply this bit only when the input supply voltage to the power FET is less than 1.1V.  <b>NOTE:</b> This bit should only be used in low-power modes where the external input supply voltage is nominally 0.9V.
28–27 -	This field is reserved.
26–23 REG2_ADJ	This field defines the adjustment bits to calibrate the target value of REG2 (REG_SOC). The adjustment is applied on top of any adjustment applied to the global reference in the MISC0 register.  0000 No adjustment 0001 + 0.25% 0010 + 0.50% 0011 + 0.75% 0100 + 1.00% 0101 + 1.25% 0110 + 1.50% 0111 + 1.75% 1000 - 0.25% 1001 - 0.50%

Table continues on the next page...

**PMU\_REG\_CORE field descriptions (continued)**

Field	Description
	1010 - 0.75% 1011 - 1.00% 1100 - 1.25% 1101 - 1.50% 1110 - 1.75% 1111 - 2.00%
22–18 REG2_TARG	This field defines the target voltage for the SOC power domain. Single-bit increments reflect 25mV core voltage steps. Some steps may not be relevant because of input supply limitations or load operation.  00000 Power gated off 00001 Target core voltage = 0.725V 10000 Target core voltage = 1.100V 11110 Target core voltage = 1.450V 11111 Power FET switched full on. No regulation.
17–14 REG1_ADJ	This field defines the adjustment bits to calibrate the target value of REG1 (REG_PU). The adjustment is applied on top of any adjustment applied to the global reference in the MISC0 register.  0000 No adjustment 0001 + 0.25% 0010 + 0.50% 0011 + 0.75% 0100 + 1.00% 0101 + 1.25% 0110 + 1.50% 0111 + 1.75% 1000 - 0.25% 1001 - 0.50% 1010 - 0.75% 1011 - 1.00% 1100 - 1.25% 1101 - 1.50% 1110 - 1.75% 1111 - 2.00%
13–9 REG1_TARG	This field defines the target voltage for the VPU/GPU power domain. Single-bit increments reflect 25mV core voltage steps. Some steps may not be relevant because of input supply limitations or load operation.  00000 Power gated off 00001 Target core voltage = 0.725V 10000 Target core voltage = 1.100V 11110 Target core voltage = 1.450V 11111 Power FET switched full on. No regulation.
8–5 REG0_ADJ	This field defines the adjustment bits to calibrate the target value of REG1 (ARM_CORE). The adjustment is applied on top of any adjustment applied to the global reference in the MISC0 register.  0000 No adjustment 0001 + 0.25% 0010 + 0.50% 0011 + 0.75%

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## PMU\_MISC0 field descriptions

Field	Description
31–29 -	This field is reserved.
28–26 CLKGATE_ DELAY	<p>This field specifies the delay between powering up the XTAL 24MHz clock and releasing the clock to the digital logic inside the analog block.</p> <p><b>NOTE:</b> Do not change the field during a low power event. This is not a field that the user would normally need to modify.</p> <p><b>NOTE:</b> Not related to PMU.</p> <p>000 0.5ms 001 1.0ms 010 2.0ms 011 3.0ms 100 4.0ms 101 5.0ms 110 6.0ms 111 7.0ms</p>
25 CLKGATE_CTRL	<p>This bit allows disabling the clock gate (always ungated) for the xtal 24MHz clock that clocks the digital logic in the analog block.</p> <p><b>NOTE:</b> Do not change the field during a low power event. This is not a field that the user would normally need to modify.</p> <p><b>NOTE:</b> Not related to PMU.</p> <p>0 <b>ALLOW_AUTO_GATE</b> — Allow the logic to automatically gate the clock when the XTAL is powered down. 1 <b>NO_AUTO_GATE</b> — Prevent the logic from ever gating off the clock.</p>
24–20 -	This field is reserved. Always set to zero.
19–18 WBCP_VPW_ THRESH	<p>This signal alters the voltage that the pwell is charged pumped to.</p> <p>00 <b>NOMINAL_BIAS</b> — Nominal output pwell bias voltage. 01 <b>PLUS_25MV</b> — Increase pwell output voltage by 25mV. 10 <b>MINUS_25MV</b> — Decrease pwell output pwell voltage by 25mV. 11 <b>MINUS_50MV</b> — Decrease pwell output pwell voltage by 50mV.</p>
17 OSC_XTALOK_ EN	<p>This bit enables the detector that signals when the 24MHz crystal oscillator is stable.</p> <p><b>NOTE:</b> Not related to PMU, Clocking content</p>
16 OSC_XTALOK	<p>Status bit that signals that the output of the 24-MHz crystal oscillator is stable. Generated from a timer and active detection of the actual frequency.</p> <p><b>NOTE:</b> Not related to PMU, clocking content.</p>
15–14 OSC_I	<p>This field determines the bias current in the 24MHz oscillator. The aim is to start up with the highest bias current, which can be decreased after startup if it is determined to be acceptable.</p> <p><b>NOTE:</b> Not related to PMU.</p>

*Table continues on the next page...*

## PMU\_MISC0 field descriptions (continued)

Field	Description
	00 <b>NOMINAL</b> — Nominal 01 <b>MINUS_12_5_PERCENT</b> — Decrease current by 12.5% 10 <b>MINUS_25_PERCENT</b> — Decrease current by 25.0% 11 <b>MINUS_37_5_PERCENT</b> — Decrease current by 37.5%
13 discon_high_ snvs	This bit forces the short between VDDHIGH_IN and VSNVS_IN to open when asserted. This is useful in power cases where SNVS_IN > VDDHIGH_IN.
12–11 STOP_MODE_ CONFIG	Configure the analog behavior in stop mode.  0x0 <b>DEEP</b> — Deep Stop Mode - All analog except rtc powered down on stop mode assertion 0x1 <b>LIGHT</b> — Light Stop Mode - All the analog domain except the LDO_1P1, LDO_2P5, and PLL3 are powered down on STOP mode assertion. If required the CCM can be configured not to power down the oscillator (XTALOSC). PLL3 can be disabled with register settings if desired.  0x2 — Reserved 0x3 — Reserved
10–8 -	This field is reserved. Reserved
7 REFTOP_ VBGUP	Status bit that signals the analog bandgap voltage is up and stable. 1 - Stable.
6–4 REFTOP_ VBGADJ	000 Nominal VBG 001 VBG+0.78% 010 VBG+1.56% 011 VBG+2.34% 100 VBG-0.78% 101 VBG-1.56% 110 VBG-2.34% 111 VBG-3.12%
3 REFTOP_ SELFBIASOFF	Control bit to disable the self-bias circuit in the analog bandgap. The self-bias circuit is used by the bandgap during startup. This bit should be set after the bandgap has stabilized and is necessary for best noise performance of analog blocks using the outputs of the bandgap.  <b>NOTE:</b> Value should be returned to zero before removing vddhigh_in or asserting bit 0 of this register (REFTOP_PWD) to assure proper restart of the circuit.  0 Uses coarse bias currents for startup 1 Uses bandgap-based bias currents for best performance.
2–1 -	This field is reserved.
0 REFTOP_PWD	Control bit to power-down the analog bandgap reference circuitry.  <b>NOTE:</b> A note of caution, the bandgap is necessary for correct operation of most of the LDO, pll, and other analog functions on the die.

### 36.7.3 Miscellaneous Register 1 (PMU\_MISC1n)

This register defines the control and status bits for miscellaneous analog blocks. The LVDS1 and LVDS2 controls below control the behavior of the anack1/1b LVDS IO.

Address: 20C\_8000h base + 160h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	IRQ_DIG_BO	IRQ_ANA_BO	IRQ_TEMPSENSE	Reserved												
W	w1c	w1c	w1c													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved		Reserved	LVDSCLK1_IBEN	Reserved	LVDSCLK1_OBEN	Reserved						LVDS1_CLK_SEL			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

## PMU\_MISC1n field descriptions

Field	Description
31 IRQ_DIG_BO	This status bit is set to one when when any of the digital regulator brownout interrupts assert. Check the regulator status bits to discover which regulator interrupt asserted.
30 IRQ_ANA_BO	This status bit is set to one when when any of the analog regulator brownout interrupts assert. Check the regulator status bits to discover which regulator interrupt asserted.
29 IRQ_TEMPSENSE	This status bit is set to one when when the temperature sensor interrupt asserts. <b>NOTE:</b> Not related to PMU, Temperature Monitor content.
28–14 -	This field is reserved.
13 -	This field is reserved. Reserved
12 LVDSCLK1_IBEN	This enables the LVDS input buffer for anack1/1b. Do not enable input and output buffers simultaneously. <b>NOTE:</b> Not related to PMU, Clocking content.
11 -	This field is reserved. Reserved
10 LVDSCLK1_OBEN	This enables the LVDS output buffer for anack1/1b. Do not enable input and output buffers simultaneously. <b>NOTE:</b> Not related to PMU, clocking content.
9–5 -	This field is reserved. Reserved
4–0 LVDS1_CLK_SEL	This field selects the clk to be routed to anack2/2b. <b>NOTE:</b> Not related to PMU.  <div> 00000      <b>ARM_PLL</b> — Arm PLL  00001      <b>SYS_PLL</b> — System PLL  00010      <b>PFD4</b> — pfd4  00011      <b>PFD5</b> — pfd5  00100      <b>PFD6</b> — pfd6  00101      <b>PFD7</b> — pfd7  00110      <b>AUDIO_PLL</b> — Audio PLL  00111      <b>VIDEO_PLL</b> — Video PLL  01000      Not functional  01001      <b>ETHERNET_REF</b> — ethernet ref clock  01010      Not Functional  01011      Not Functional  01100      <b>USB1_PLL</b> — USB1 PLL clock  01101      <b>USB2_PLL</b> — USB2 PLL clock  01110      <b>PFD0</b> — pfd0  01111      <b>PFD1</b> — pfd1  10000      <b>PFD2</b> — pfd2  10001      <b>PFD3</b> — pfd3  10010      <b>XTAL</b> — xtal </div>

## PMU Memory Map/Register Definition

### PMU\_MISC2n field descriptions

Field	Description
31–30 VIDEO_DIV	<p>Post-divider for video. The output clock of the video PLL should be gated prior to changing this divider to prevent glitches. This divider is feed by PLL_VIDEOOn[POST_DIV_SELECT] to achieve division ratios of / 1, /2, /4, /8, and /16.</p> <p><b>NOTE:</b> Not related to PMU. See <a href="#">Clock Controller Module (CCM)</a> for more information.</p> <p>00 divide by 1 (Default)  01 divide by 2  10 divide by 1  11 divide by 4</p>
29–28 REG2_STEP_TIME	<p>Number of clock periods (24MHz clock).</p> <p>00 <b>64_CLOCKS</b> — 64  01 <b>128_CLOCKS</b> — 128  10 <b>256_CLOCKS</b> — 256  11 <b>512_CLOCKS</b> — 512</p>
27–26 REG1_STEP_TIME	<p>Number of clock periods (24MHz clock).</p> <p>00 <b>64_CLOCKS</b> — 64  01 <b>128_CLOCKS</b> — 128</p>

Table continues on the next page...

## PMU\_MISC2n field descriptions (continued)

Field	Description
	10 <b>256_CLOCKS</b> — 256 11 <b>512_CLOCKS</b> — 512
25–24 REG0_STEP_ TIME	Number of clock periods (24MHz clock).  00 <b>64_CLOCKS</b> — 64 01 <b>128_CLOCKS</b> — 128 10 <b>256_CLOCKS</b> — 256 11 <b>512_CLOCKS</b> — 512
23 AUDIO_DIV_ MSB	MSB of Post-divider for Audio PLL. The output clock of the video PLL should be gated prior to changing this divider to prevent glitches. This divider is feed by PLL_AUDION[POST_DIV_SELECT] to achieve division ratios of /1, /2, /4, /8, and /16.  <b>NOTE:</b> MSB bit value pertains to the first bit, please program the LSB bit (bit 15) as well to change divider value  <b>NOTE:</b> Not related to PMU. See <a href="#">Clock Controller Module (CCM)</a> for more information.  00 divide by 1 (Default) 01 divide by 2 10 divide by 1 11 divide by 4
22 REG2_OK	Signals that the voltage is above the brownout level for the SOC supply. 1 = regulator output > brownout_target
21 REG2_ENABLE_ BO	Enables the brownout detection.
20 -	This field is reserved.
19 REG2_BO_ STATUS	Reg2 brownout status bit.
18–16 REG2_BO_ OFFSET	This field defines the brown out voltage offset for the xPU power domain. IRQ_DIG_BO is also asserted. Single-bit increments reflect 25mV brownout voltage steps. The reset brown-offset is 175mV below the programmed target code. Brownout target = OUTPUT_TRG - BO_OFFSET. Some steps may be irrelevant because of input supply limitations or load operation.  100 Brownout offset = 0.100V 111 Brownout offset = 0.175V
15 AUDIO_DIV_LSB	LSB of Post-divider for Audio PLL. The output clock of the video PLL should be gated prior to changing this divider to prevent glitches. This divider is feed by PLL_AUDION[POST_DIV_SELECT] to achieve division ratios of /1, /2, /4, /8, and /16.  <b>NOTE:</b> LSB bit value pertains to the last bit, please program the MSB bit (bit 23) as well, to change divider value  <b>NOTE:</b> Not related to PMU. See <a href="#">Clock Controller Module (CCM)</a> for more information.  00 divide by 1 (Default) 01 divide by 2 10 divide by 1 11 divide by 4

Table continues on the next page...

## PMU\_MISC2n field descriptions (continued)

Field	Description
14 -	This field is reserved. Reserved
13 REG1_ENABLE_ BO	Enables the brownout detection.
12 -	This field is reserved.
11 REG1_BO_ STATUS	Reg1 brownout status bit. 1 Brownout, supply is below target minus brownout offset.
10–8 REG1_BO_ OFFSET	This field defines the brown out voltage offset for the xPU power domain. IRQ_DIG_BO is also asserted. Single-bit increments reflect 25mV brownout voltage steps. The reset brown-offset is 175mV below the programmed target code. Brownout target = OUTPUT_TRG - BO_OFFSET. Some steps may be irrelevant because of input supply limitations or load operation.  100 Brownout offset = 0.100V 111 Brownout offset = 0.175V
7 PLL3_disable	Default value of "0". Should be set to "1" to turn off the USB-PLL(PLL3) in run mode. <b>NOTE:</b> Not related to PMU. See <a href="#">Clock Controller Module (CCM)</a> for more information.
6 -	This field is reserved.
5 REG0_ENABLE_ BO	Enables the brownout detection.
4 -	This field is reserved.
3 REG0_BO_ STATUS	Reg0 brownout status bit. 1 Brownout, supply is below target minus brownout offset.
2–0 REG0_BO_ OFFSET	This field defines the brown out voltage offset for the CORE power domain. IRQ_DIG_BO is also asserted. Single-bit increments reflect 25mV brownout voltage steps. Some steps may be irrelevant because of input supply limitations or load operation.  100 Brownout offset = 0.100V 111 Brownout offset = 0.175V

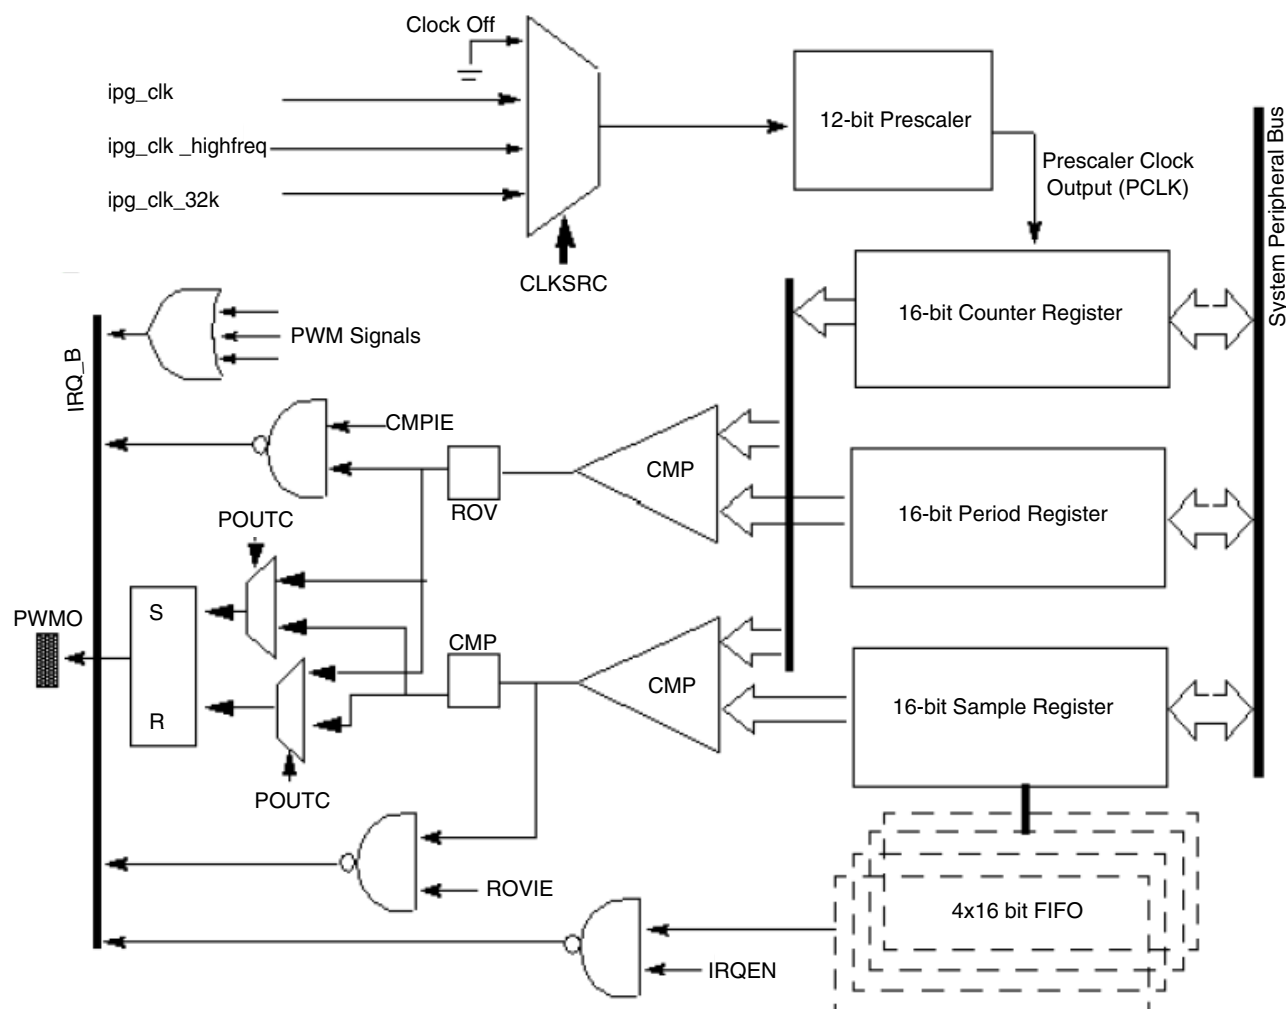

## **Chapter 37**

# **Pulse Width Modulation (PWM)**

### **37.1 Overview**

The Pulse Width Modulation (PWM) has a 16-bit counter, and is optimized to generate sound from stored sample audio images and it can also generate tones. It uses 16-bit resolution and a 4 x 16 data FIFO.

This section presents an overview of the PWM. A block diagram of the PWM module is shown in the figure below.

### Figure 37-1. Pulse-Width Modulator Block Diagram

The following features characterize the PWM:

- 16-bit up-counter with clock source selection
- 4 x 16 FIFO to minimize interrupt overhead
- 12-bit prescaler for division of clock
- Sound and melody generation
- Active high or active low configured output
- Can be programmed to be active in low-power mode
- Can be programmed to be active in debug mode
- Interrupts at compare and rollover

## 37.2 External Signals

The PWM follows IP Bus protocol when interfacing with the processor core. PWM does not have any interface signals with any other block inside the chip except for clock and reset inputs from the Clock Control Module (CCM), System Reset Controller (SRC), and interrupt signals to the processor interrupt handler. There is a single output signal.

The following table outlines the external signals.

**Table 37-1. PWM External Signals**

Signal	Description	Pad	Mode	Direction
PWM1_OUT	This is the PWM1 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	EPDC_SDCE2	ALT2	O
		LCD_DAT0	ALT3	
		PWM1	ALT0	
		UART1_RXD	ALT1	
		HSIC_DAT	ALT2	
PWM2_OUT	This is the PWM2 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	EPDC_SDCE3	ALT2	O
		LCD_DAT1	ALT3	
		UART1_TXD	ALT1	
		HSIC_STROBE	ALT2	
PWM3_OUT	This is the PWM3 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	AUD_TXFS	ALT1	O
		EPDC_SDCE0	ALT2	
		LCD_DAT2	ALT3	
		REF_CLK_24M	ALT2	
PWM4_OUT	This is the PWM4 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	AUD_MCLK	ALT1	O
		EPDC_GDSP	ALT1	
		EPDC_SDCE1	ALT2	
		FEC_REF_CLK	ALT3	
		LCD_CLK	ALT4	
		LCD_DAT3	ALT3	
		REF_CLK_32K	ALT2	

## 37.3 Clocks

The table found here describes the clock sources for PWM.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 37-2. PWM Clocks**

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_32k	ckil_sync_clk_root	low-frequency reference clock (32kHz)
ipg_clk_highfreq	perclk_clk_root	high-frequency reference clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

The clock that feeds the prescaler can be selected from:

- High-frequency reference clock (ipg\_clk\_highfreq) pat\_ref or CKIH

This is a high frequency clock, provided by the Clock Control Module (CCM). This clock should be on in the low power mode when the ipg\_clk is turned off. Thus, the PWM can be run on this clock in the low power mode.

- Low-frequency reference clock (ipg\_clk\_32k, CKIL)

This is the 32 KHz low reference clock which is provided by the CCM. This clock should be on in the low power mode when ipg\_clk is turned off. Thus, PWM can be run on this clock in the low power mode.

- Peripheral clock (ipg\_clk)

This clock should be on in normal operations. In low power mode, it can be switched off.

- Peripheral access clock (ipg\_clk\_s)

This clock is used for register read/write.

The clock input source is determined by the PWM control register field PWM\_CR[CLKSRC]. The CLKSRC value should only be changed when the PWM is disabled.

A change in the value of the PRESCALER field of the control register is immediately reflected on its output clock frequency.

## 37.4 Functional Description

The following sections detail the PWM operation and function.

### 37.4.1 Operation

The output of the PWM is a toggling signal whose frequency and duty cycle can be modulated by programming the appropriate registers. It has a 16-bit up counter which counts from 0x0000 until the counter value equals the PWM\_PR + 1. After this match occurs the counter is reset to 0x0000.

At the beginning of a count period cycle, the PWM0 pin is set to one (default) and the counter begins counting up from 0x0000. The sample value in the sample FIFO is compared on each count of prescaler clock. When the sample and count values match, the PWM0 signal is cleared to zero (default). The counter continues counting until the period match occurs and subsequently another period cycle begins.

When the PWM is enabled, the counter starts running and generates an output with the reset values in the period and sample registers. It is recommended that the programming of these registers be done before PWM is enabled.

A hardware reset results in all the PWM count and sample registers being cleared and the FIFO being flushed. The control register shows that FIFO is empty and it can be written into, and the PWM is disabled. A software reset has the same results, however the state of the STOPEN, DOZEN, WAITEN, and DBGEN bits in the control register are not affected. Software reset can be asserted even when the PWM is in disabled state.

#### 37.4.1.1 FIFO

Digital sample values can be loaded into the pulse-width modulator as 16-bit words. The endianness can be changed using the BCTR and HCTR bits of the control register. A 4-word (16-bit) FIFO minimizes interrupt overhead. A maskable interrupt is generated when the number of data words fall below the water level set by the FWM field in the control register.

A write to the PWM\_SAR sample register results in the value being stored into the FIFO if it is not full. A write when the FIFO is full sets FWE (FIFO write error) bit in the status register and the FIFO contents remain unchanged. The FIFO can be written at any time, but can be read only when the PWM is enabled. The PWM\_SR[FIFOAV] field shows how many data words are currently contained in the FIFO and whether or not it can be written into.

A read on the sample register yields the current FIFO value that is being used, or will be used, by the PWM for generation on the output signal. Therefore, a write and a subsequent read on the sample register may result in different values being obtained.

### 37.4.1.2 Rollover and Compare Event

The counter is reset to 0x0000 after its value equals the PWM\_PR[PERIOD] + 1 and resumes counting thereafter. This event is referred to as a rollover. For example, if PWM\_PR[PERIOD] = 0x0000, the counter is reset when it equals 0x0001. When PWM\_PR[PERIOD] = 0xFFFF or 0xFFFE, the counter is reset when it equals 0xFFFF. For more information, see the PWM Period Register (PWM\_PR) description.

During a rollover event the output is either set (default), reset or has no effect according to the programming of the POUTC field in the control register. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

When the counter value reaches the sample value, the output of the PWM is reset (default), set or has no effect according to the programming of the POUTC field of control register. This event is referred to as a compare event. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

If the rollover event sets the PWM output signal, the compare event will reset it and vice versa for a particular programming configuration of POUTC field.

### 37.4.1.3 Low Power Mode Behavior

In low power mode, if the clock from the selected clock source is available, the PWM counter continues to run and an output is produced, depending on whether the control bit for that mode is set or not. In the absence of the clock itself, or if the corresponding low power bit in the control register is 0, the counter is reset and resumes counting when it exits the low power mode.

### 37.4.1.4 Debug Mode Behavior

In debug mode, PWM has the option of continuing to run or be halted. If the DBGEN bit is not set in the PWM\_PWMCR, the PWM is halted. If the DBGEN bit is set, then the PWM will continue to run in the debug mode.

## 37.5 Enable Sequence for the PWM

The sequence found here should be used to enable the PWM.

1. Configure the desired settings for the PWM Control Register (PWMx\_PWMCR) while keeping the PWM disabled (PWMx\_PWMCR[0]=0).
2. Enable the desired interrupts in the PWM Interrupt Register (PWMx\_PWMIR).
3. One to three initial samples may be written to the PWM Sample Register (PWMx\_PWMSAR). The initial sample values will be loaded into the PWM FIFO even if the PWM is not yet enabled. Do not write a 4th sample because the FIFO will become full and trigger a FIFO Write Error (FWE). This error will prevent the PWM from starting once it is enabled.
4. Check the FIFO Write Error status bit (FWE), the Compare status bit (CMP) and the Roll-over status bit (ROV) in the PWM Status Register (PWMx\_PWMSR) to make sure they are all zero. Any non-zero status bits should be cleared by writing a 1 to them.
5. Write the desired period to the PWM Period Register (PWMx\_PWMPR).
6. Enable the PWM by writing a 1 to the PWM Enable bit, PWMx\_PWMCR[0], while maintaining the other register bits in their previously configured state.

## 37.6 Disable Sequence for the PWM

The PWM can be disabled at any time by clearing the PWM enable bit, PWMx\_PWMCR[0] to 0.

Any data remaining in the FIFO will not be produced at the PWM output after the PWM has been disabled and will remain in the FIFO until the PWM is enabled again. A software reset (setting PWMx\_PWMCR[3] to 1) or a hardware reset will clear the FIFO and any remaining data will be lost.

## 37.7 PWM Memory Map/Register Definition

The PWM includes six user-accessible 32-bit registers.

**PWM memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
208_0000	PWM Control Register (PWM1_PWMCR)	32	R/W	0000_0000h	<a href="#">37.7.1/2267</a>

### PWMx\_PWMCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–26 FWM	FIFO Water Mark. These bits are used to set the data level at which the FIFO empty flag will be set and the corresponding interrupt generated  00 FIFO empty flag is set when there are more than or equal to 1 empty slots in FIFO 01 FIFO empty flag is set when there are more than or equal to 2 empty slots in FIFO 10 FIFO empty flag is set when there are more than or equal to 3 empty slots in FIFO 11 FIFO empty flag is set when there are more than or equal to 4 empty slots in FIFO
25 STOPEN	Stop Mode Enable. This bit keeps the PWM functional while in stop mode. When this bit is cleared, the input clock is gated off in stop mode. This bit is not affected by software reset. It is cleared by hardware reset.  0 Inactive in stop mode 1 Active in stop mode
24 DOZEN	Doze Mode Enable. This bit keeps the PWM functional in doze mode. When this bit is cleared, the input clock is gated off in doze mode. This bit is not affected by software reset. It is cleared by hardware reset.  0 Inactive in doze mode 1 Active in doze mode
23 WAITEN	Wait Mode Enable. This bit keeps the PWM functional in wait mode. When this bit is cleared, the input clock is gated off in wait mode. This bit is not affected by software reset. It is cleared by hardware reset.

Table continues on the next page...

**PWMx\_PWMCR field descriptions (continued)**

Field	Description
	0 Inactive in wait mode 1 Active in wait mode
22 DBGEN	Debug Mode Enable. This bit keeps the PWM functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode. This bit is not affected by software reset. It is cleared by hardware reset.  0 Inactive in debug mode 1 Active in debug mode
21 BCTR	Byte Data Swap Control. This bit determines the byte ordering of the 16-bit data when it goes into the FIFO from the sample register.  0 byte ordering remains the same 1 byte ordering is reversed
20 HCTR	Half-word Data Swap Control. This bit determines which half word data from the 32-bit IP Bus interface is written into the lower 16 bits of the sample register.  0 Half word swapping does not take place 1 Half words from write data bus are swapped
19–18 POUTC	PWM Output Configuration. This bit field determines the mode of PWM output on the output pin.  00 Output pin is set at rollover and cleared at comparison 01 Output pin is cleared at rollover and set at comparison 10 PWM output is disconnected 11 PWM output is disconnected
17–16 CLKSRC	Select Clock Source. These bits determine which clock input will be selected for running the counter. After reset the system functional clock is selected. The input clock can also be turned off if these bits are set to 00. This field value should only be changed when the PWM is disabled  00 Clock is off 01 ipg_clk 10 ipg_clk_highfreq 11 ipg_clk_32k
15–4 PRESCALER	Counter Clock Prescaler Value. This bit field determines the value by which the clock will be divided before it goes to the counter.  0x000 Divide by 1 0x001 Divide by 2 0xff Divide by 4096
3 SWR	Software Reset. PWM is reset when this bit is set to 1. It is a self clearing bit. A write 1 to this bit is a single wait state write cycle. When the block is in reset state this bit is set and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values except for the STOPEN, DOZEN, WAITEN, and DBGEN bits in this control register.  0 PWM is out of reset 1 PWM is undergoing reset
2–1 REPEAT	Sample Repeat. This bit field determines the number of times each sample from the FIFO is to be used.  00 Use each sample once 01 Use each sample twice 10 Use each sample four times 11 Use each sample eight times

*Table continues on the next page...*

**PWMx\_PWMCR field descriptions (continued)**

Field	Description
0 EN	<p>PWM Enable. This bit enables the PWM. If this bit is not enabled, the clock prescaler and the counter is reset. When the PWM is enabled, it begins a new period, the output pin is set to start a new period while the prescaler and counter are released and counting begins.</p> <p>To make the PWM work with softreset and disable/enable, users can do software reset by setting the SWR bit, wait software reset done, configure the registers, and then enable the PWM by setting this bit to "1"</p> <p>Users can also disable/enable the PWM if PWM would like to be stopped and resumed with same registers configurations .</p> <p>0    PWM disabled 1    PWM enabled</p>

**37.7.3 PWM Status Register (PWMx\_PWMSR)**

The PWM status register (PWM\_PWMSR) contains seven bits which display the state of the FIFO and the occurrence of rollover and compare events. The FIFOAV bit is read-only but the other four bits can be cleared by writing 1 to them. The FE, ROV, and CMP bits are associated with FIFO-Empty, Roll-over, and Compare interrupts, respectively.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

**PWMx\_PWMSR field descriptions**

Field	Description
31–7 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
6 FWE	<p>FIFO Write Error Status. This bit shows that an attempt has been made to write FIFO when it is full.</p> <p>0    FIFO write error not occurred 1    FIFO write error occurred</p>
5 CMP	<p>Compare Status. This bit shows that a compare event has occurred.</p> <p>0    Compare event not occurred 1    Compare event occurred</p>

*Table continues on the next page...*

**PWMx\_PWMSR field descriptions (continued)**

Field	Description
4 ROV	Roll-over Status. This bit shows that a roll-over event has occurred.  0 Roll-over event not occurred 1 Roll-over event occurred
3 FE	FIFO Empty Status Bit. This bit indicates the FIFO data level in comparison to the water level set by FWM field in the control register.  0 Data level is above water mark 1 When the data level falls below the mark set by FWM field
2–0 FIFOAV	FIFO Available. These read-only bits indicate the data level remaining in the FIFO. An attempted write to these bits will not affect their value and no transfer error is generated.  000 No data available 001 1 word of data in FIFO 010 2 words of data in FIFO 011 3 words of data in FIFO 100 4 words of data in FIFO 101 unused 110 unused 111 unused

**37.7.4 PWM Interrupt Register (PWMx\_PWMIR)**

The PWM Interrupt register (PWM\_PWMIR) contains three bits which control the generation of the compare, rollover and FIFO empty interrupts.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0														CIE	RIE
W																FIE
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PWMx\_PWMIR field descriptions**

Field	Description
31–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 CIE	Compare Interrupt Enable. This bit controls the generation of the Compare interrupt.

*Table continues on the next page...*

**PWMx\_PWMIR field descriptions (continued)**

Field	Description
	0 Compare Interrupt not enabled 1 Compare Interrupt enabled
1 RIE	Roll-over Interrupt Enable. This bit controls the generation of the Rollover interrupt.  0 Roll-over interrupt not enabled 1 Roll-over Interrupt enabled
0 FIE	FIFO Empty Interrupt Enable. This bit controls the generation of the FIFO Empty interrupt.  0 FIFO Empty interrupt disabled 1 FIFO Empty interrupt enabled

**37.7.5 PWM Sample Register (PWMx\_PWMSAR)**

The PWM sample register (PWM\_PWMSAR) is the input to the FIFO. 16-bit words are loaded into the FIFO. The FIFO can be written at any time, but can be read only when the PWM is enabled. The PWM will run at the last set duty-cycle setting if all the values of the FIFO has been utilized, until the FIFO is reloaded or the PWM is disabled. When a new value is written, the duty cycle changes after the current period is over.

A value of zero in the sample register will result in the PWMO output signal always being low/high (POUTC = 00 it will be low and POUTC = 01 it will be high), and no output waveform will be produced. If the value in this register is higher than the PERIOD + 1, the output will never be set/reset depending on POUTC value.

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																SAMPLE															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PWMx\_PWMSAR field descriptions**

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–0 SAMPLE	Sample Value. This is the input to the 4x16 FIFO. The value in this register denotes the value of the sample being currently used.

### 37.7.6 PWM Period Register (PWMx\_PWMPR)

The PWM period register (PWM\_PWMPR) determines the period of the PWM output signal. After the counter value matches PERIOD + 1, the counter is reset to start another period.

$$PWMO\text{ (Hz)} = PCLK(\text{Hz}) / (\text{period} + 2)$$

A value of zero in the PWM\_PWMPR will result in a period of two clock cycles for the output signal. Writing 0xFFFF to this register will achieve the same result as writing 0xFFFE.

A change in the period value due to a write in PWM\_PWMPR results in the counter being reset to zero and the start of a new count period.

**NOTE**

Settings PWM\_PWMPR to 0xFFFF when PWMx\_PWMCR REPEAT bits are set to non-zero values is not allowed.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PWMx\_PWMPR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–0 PERIOD	Period Value. These bits determine the Period of the count cycle. The counter counts up to [Period Value] +1 and is then reset to 0x0000.

### 37.7.7 PWM Counter Register (PWMx\_PWMCNR)

The read-only pulse-width modulator counter register (PWM\_PWMCNR) contains the current count value and can be read at any time without disturbing the counter.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PWMx\_PWMCNR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–0 COUNT	Counter Value. These bits are the counter register value and denotes the current count state the counter register is in.

# Chapter 38

## Pixel Pipeline (PXP)

### 38.1 Overview

This document describes the micro-architecture for the proposed Pixel Pipeline used to process graphics buffers or composite video and graphics data before sending to an LCD display or TV encoder.

The goal is to minimize the memory footprint required for the display pipeline and provide an area and performance optimized engine that can meet the needs of both SDRAM-less and SRAM-based systems.

The PXP targets the integration of several independent processing stages into a cohesive strategy to create a pixel pipeline that is flexible enough to handle the requirements of current and future chips.

The PXP combines scaling, color space conversion (or CSC), alpha-blending, secondary color space conversion (or CSC2), pixel conversion lookup memory table (or LUT), and rotation into a single processing engine, as shown in the diagram below. By integrating multiple blocks, intermediate buffer operations to external memory are removed, reducing external memory bandwidth, power, and software control complexity.

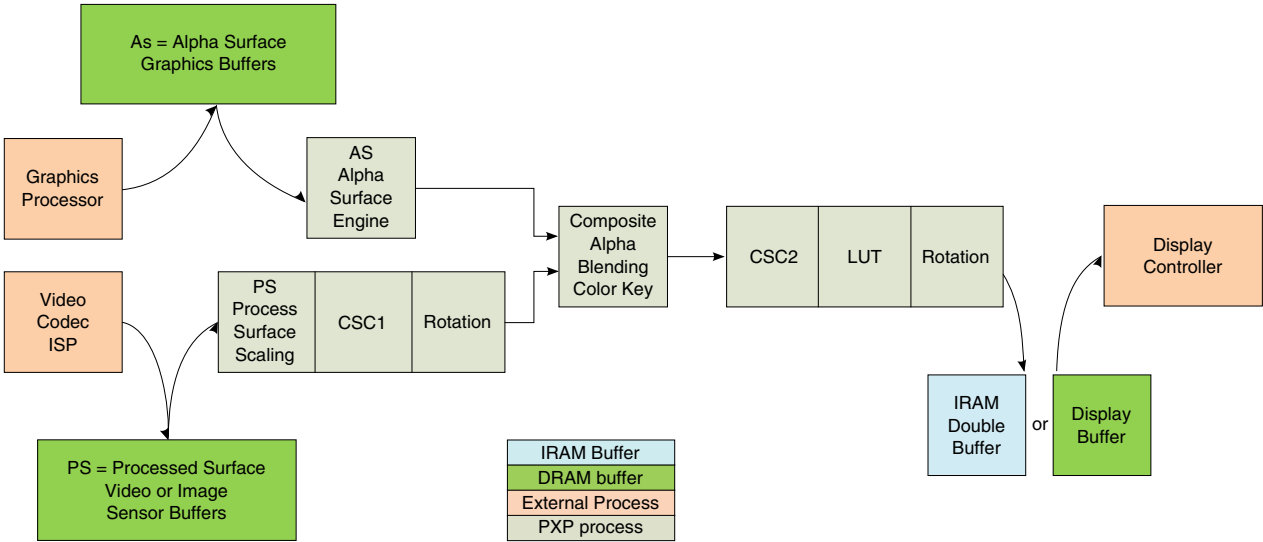

Figure 38-1. PXP Architecture

## 38.2 Clocks

The following table describes the clock sources for PXP. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

Table 38-1. PXP Clocks

Clock name	Clock Root	Description
clk	pxp_axi_clk_root	PXP clock

## 38.3 Top-level architecture

The PXP will consist of several pipelined blocks that perform the video source frame scaling, color space conversion, alpha-blending/color key algorithm, secondary CSC, pixel correction, and input/output rotation.

The entire pipeline will operate within the requirements of the PXP architecture, and will thus perform operations on either 8x8 or 16x16 pixel blocks in the representative source buffers. The entire pipeline will operate within the context of two iteration counters that iterate through the appropriate grid of input blocks to produce the rotated output grid blocks in scan-line order.

Figure 38-1 above shows the high-level architecture of the scaling, color space conversion, blending, pixel correction and rotation engines. The Alpha Formatter fetches one RGB graphics plane alpha surface, or AS. The Scaling engine fetches a single processed surface, or PS, which can be blended with the AS surface. Although the PXP processes NxN pixel macro blocks, each of the AS or PS surfaces can have any pixel alignment within the output buffer. There are no restrictions and any pixel coordinates within the output buffer are valid. The upper left origin of the output buffer is defined as pixel 0,0. The upper left and lower right coordinates for each of the AS and PS surfaces are inclusive within the output buffer.

Figure 38-2 represents a sample output buffer configuration with both an AS and PS surfaces included. The alignment of each AS and PS surface within the output buffer can be at any arbitrary pixel locations. For example, the PS surface has an upper left coordinate (ULC) of 2,2 and a lower right coordinate (LRC) at pixel 13,13. The maximum value for the ULC and LRC for each of the AS and PS surfaces is bounded by the LRC of the output buffer, 15,15 for this example.

**Figure 38-2. Sample output buffer configuration**

The AS engine supports RGB pixel formats, and the PS engine supports RGB, YUV, and YCbCr pixel formats and variants of these pixel types. The CSC1 can be used to convert to RGB pixel formats so that the PS surface can be blended with the AS surfaces in the compositing engine in the RGB color space. There is a single rotation engine in the PXP with a programmable location within the PXP pipeline. Rotation can occur at the output stage after image composition occurs, or it can occur at the output of the PS engine. In the first scenario, all the data produced by the AS and PS engines will be rotated. When the rotation module is programmed to rotate only PS images, the AS is not rotated, and AS pixels are combined with rotated PS surfaces. The CSC2 unit can convert to any color space for final output. Pixels can be corrected using a programmable LUT resource to achieve any desired pixels effects.

### 38.3.1 Processing Details

The PXP architecture has been driven primarily by the requirement that the output buffer must be processed and rotated without intermediate frame buffer stored in external memory.

This reduces the use of external memory bandwidth requirements thus reducing overall system power consumed.

Since the output of the rotation block must be NxN pixel blocks in scan order, the entire pipeline will operate on NxN pixel blocks. In essence, the pipeline will be able to operate on blocks in a random access fashion, but the entire pipeline will operate within the context of two iteration counters that will iterate through the horizontal and vertical input blocks to generate the required output block.

#### Processing Pipeline

The control block will coordinate the processing of the pixel blocks within the source and destination image buffers. It begins by issuing a command to each stage of the pipeline requesting that operations be done for the block at offset x, y. When the block accepts the command, it asserts its acknowledge signal for a single cycle to indicate the acceptance and allow the control unit to move to the next block.

When the PS and AS fetch engines have received a command, they will fetch the required data and place it into their fetch buffers. If compositing the RGB AS surface with the PS surface, then the output of the PS engine needs to be converted to the RGB color space using CSC1, since all compositing occurs in the RGB color space. For YUV output pixel formats, the CSC1 unit can be enabled to convert pixels into the RGB space for subsequent compositing with AS pixels. Then, the CSC2 module can convert the resulting pixels back into the YUV output color space. If the final output color space is YUV and there is no compositing required (AS not present, for example), then both the

CSC units can be bypassed and the pixel data path will pass the YUV pixels to the rotation engine. For YUV output formats, scaling operations, LUT, and rotation operations are still valid, but blending RGB AS surfaces with YUV PS surfaces is NOT supported. The two CSC units in the overall pixel data path must be used to achieve the desired source frame compositing and output pixel formatting.

The alpha blender/color key module will process a pixel any time that both inputs present valid data.

A handshake will be created between each stage and a pipeline controller to handle the advance of the pipeline and generation of the iteration counters. The pipeline controller will also maintain the interlocks with the LCD interface for the case where the LCD display and pixel pipeline use the SRAM to maintain the double buffer block intermediate buffer .

### 38.3.2 Scaling Operation

The scaling engine operates on YUV (or YCbCr) 422 or 420 and any RGB formatted pixels. Each color plane is sourced from color planes indicated by different base address registers.

The scaling source data can be stored as 3 individual planes for each Y, U, and V data, stored as two planes as a single Y and interleaved UV plane, or stored as a single plane with YUV/RGB interleaved on a per byte basis.

The scaled output image is presented to the CSC module as YUV444 or RGB888 pixels with a single byte for each color channel. The scaler can reduce an input image by a maximum factor of 16. In this case, the output image will be 1/16 the dimension of the input image in each of the X and Y axis. There are no limits, essentially, on increasing the source image size. The theoretical maximum increase is 4096 since a 12 bit fractional step function is used when scaling an input image. Scaling in either axis, X or Y is independent, so a source image can appear stretched in either direction.

All source images pass through the scale engine. The PXP alpha blend module and AS pixel streams are in the RGB888 format, so PS pixel buffers must be converted to the RGB888 format for alpha blending. The scaling engine works with the CSC1 module to translate YUV/YCbCr pixel formats to RGB888 for output frame buffer compositing using the alpha blender. The CSC2 module can be bypassed or enabled to convert pixels to any output color space. In the case of processing RGB pixels in the PS engine, the CSC1 unit can be bypassed so compositing can occur in the alpha engine.

The scaling operation is divided into two scaling steps. The first step is a decimation scaler, and the second step is a bilinear filter. The decimation filter provide a maximum down scaling factor of 8, and the subsequent bilinear filter provides a maximum scaling factor of 2. Combined, the maximum scaling factor can be up to 16. The decimation and bilinear scaling engines are independently programmable. There is also an initial offset that is programmable to allow more source data to be considered in the bilinear scaling engine.

### 38.3.3 Decimation Image Scaling

The first of two scaling engines is the decimation filter.

The intent of the decimation filter is to use as much source data as is possible to create the output image frame buffer. The decimation filter simply discards certain pixels from the source PS image depending on the reduction selected.

For RGB pixel formats, each color channel is treated equally since there is the same amount of pixel data within each color plane. For YUV422/420 formats, the chroma samples are already subsampled by 2. In these decimation scenarios, the chroma decimation factor is adjusted to account for the pre-decimation of the chroma samples. For example, since YUV422 is already sub-sampled by 2 horizontally, an X decimation factor of 2 does not apply to the YUV422 pixels in the X direction. All the chroma samples are passed on to the bilinear filter in this case. As another example, an X decimation factor of 4 will decimate the chroma samples by 2, since this factor combined with the pre-decimation factor of 2 in the pixel source buffers totals an overall decimation factor of 4.

The following example will show which pixels (in green) in a source RGB buffer that are passed to the bilinear filter for an X decimation factor of 2 and a Y decimation factor of 4. All pixels coincident with dashed lines are discarded.

**Figure 38-3. RGB decimation X /2, Y /4**

Using the same decimation factor as the above scenario for RGB pixels, but using YUV420 source buffers, it can be shown that the decimation factor for the Y and UV components of data are decimated differently. This is due to the pre-decimation of the chroma samples in the source frame buffers. Figure 4: YUV420 decimation X /2, Y /4 indicates that the U/V samples in the X direction are not decimated, but the Y samples in the X direction are decimated by the factor of 2.

**Figure 38-4. YUV420 decimation X /2, Y /4**

### 38.3.4 Bilinear Image Scaling Filter

The PXP implements a bilinear scaling filter to resize an input image to a different resolution for display output.

The bilinear filter is a weighted average of the four nearest pixels that can be sourced to approximate the pixel in the output frame buffer.

When scaling YUV data, the UV values are offset by 0x80 (top bit inverted) to shift the signed UV bits into an unsigned equivalent with a range of 0 to 255. YCbCr data does not have to be shifted since it is defined as an unsigned byte. The REG\_CSC1\_COEF0[YCBCR\_MODE] bit controls whether this operation is applied to the input UV bytes.

After scaling, the offset is removed so that the range for UV data is signed from -128 to 127.

The reason for this adjustment is based on the implementation of an unsigned scaling engine, and therefore, is to ensure that the scaled values are handled properly. Consider the following table:

Format	pixel0	pixel1	average	Result
decimal	-2	+2	0	Correct
CbCr	0x7E	0x82	0x80	Correct (0x80 is 0 in CbCr)
UV	0xFE	0x02	0x80	Incorrect (0x80 is -128 in UV)
decimal	-32	+16	-8	Correct
CbCr	0x60	0x90	0x78	Correct (0x78 is -8 in CbCr)
UV	0xE0	0x10	0x78	Incorrect (0x78 is +120 in UV)

To compute the output pixel value at position as indicated by P, consider the diagram below.

**Figure 38-5. Output Pixel Value**

A step function is used to indicate the position of the pixel "P" in the output frame. This position may not coincide with a single pixel position in the input frame buffer. In this case, the four closest pixels in the input frame are used to approximate the value of the pixel in the output frame.

The PXP scaler first computes a linear filter in the X axis to create the two intermediate pixel values Px0 and Px1. The step function's X fractional component is used to provide the weighting factor for blending p00 with p10 to provide Px0. Likewise, Px1 is also derived from a linear filter using p01 and p11.

The equations for Px0 and Px1 are as follows:

$$Px0 = p00*(1-Rx) + p10*Rx$$

$$Px1 = p01*(1-Rx) + p11*Rx$$

The PXP scaler uses the intermediate X pixels Px0 and Px1 and implements a bilinear filter on these two pixel values to produce the final pixel value at position P. The remainder of the step function for the Y axis is used to compute the weighted average pixel result. The equation for final filtered pixel is:

$$P = Px0*(1-Ry) + Px1*Ry$$

### 38.3.5 YUV 4:2:2 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:2 formats. There are twice as many Y luma samples then U and V chroma samples horizontally.

**Figure 38-6. YUV Sample Positioning, 4:2:2**

Consider the scaled output pixel  $P_s$  (pixel scaled) which has an accumulated step function of  $X=1.5$  and  $Y=0.5$ . The remainder for the step function is  $R_x = 0.5$  and  $R_y = 0.5$ . Or, the sub pixel position of output pixel  $P_s$  is half way between line 0 and 1 and half way between column 1 and 2.

The Y output component of  $P_s$  is simply the bilinear function of the four nearest Y samples from the input image. Specifically, the Y values at [1,0], [2,0], [1,1], and [2,1] are used to compute the Y for  $P_s$ .

For the U and V components of  $P_s$ , there are no samples present in the column position 1. The bilinear filter uses chroma components located at [0,0], [2,0], [0,1] and [2,1]. Since the chroma components are not sub sampled vertically, the remainder used to combine pixels vertically is  $R_y=0.5$  (the same as for Y). However, horizontally, the scaling engine shifts the remainder by a factor of 2. So an X axis step function value of  $X=1.5$  has a remainder  $R_x=0.75$ . Source chroma values are not replicated, they are completely interpolated using the four nearest chroma samples to approximate U and V at  $P_s$ .

### 38.3.6 YUV 4:2:0 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:0 formats. Chroma is sub sampled both horizontally and vertically. In this format, the chroma frame buffers contain  $\frac{1}{4}$  the data that the luma frame buffers store.

**Figure 38-7. YUV Sample Positioning, 4:2:0**

The Y output component for all scaled pixels in 4:2:0 formats are the same as for the 4:2:2 pixel formats.

The U and V output components have two considerations when computing the output pixel  $P_s$ .

1. All chroma samples from the input source image are shifted left and up by  $\frac{1}{2}$  a sample position of the input pixel matrix.
2. Odd scan lines are replicated using the previous even chroma scan line values. So, output image chroma values that map between even to odd scan lines are replicated in the vertical axis. In contrast, output image chroma values between odd to even scan lines are interpolated vertically.

The chroma values are interpolated horizontally as in the 4:2:2 pixel format.

As an example, consider the interpolated pixel  $P_s$  in the 4:2:0 diagram above. For the Y component, the interpolated output luma is a function of the Y values in the source frame buffer at position [1,0], [2,0], [1,1], [2,1].

For the U and V interpolated samples, the chroma values on scan line position 0.5 are shifted so that they coincide with the even luma sample points. They are also replicated so that a single chroma scan line is used twice. The chroma scan line at 0.5 is replicated to represent the 4:2:2 sample points for scan line 0 and 1. The chroma scan line at 2.5 is replicated to represent the 4:2:2 sample points for scan line 2 and 3. This pattern of chroma replication occurs for the entire source frame buffer during the scaling operation.

**Figure 38-8. Scaled Chroma Computation Examples**

The preceding diagram has two examples for the computation of the scaled chroma output pixel. For chroma at output position PsA (vertical position 0.5), interpolation occurs in the X axis using chroma values at column 0 and column 2. However, since line 0 and line 1 have equal chroma values due to chroma line replication, scaling in the Y axis results in replication of chroma values.

For chroma at output position PsB (vertical position 1.5), interpolation occurs in both the X and Y axis. The Y axis is an interpolation since the chroma values copied to scan line 1 and 2 and not the same.

In summary, any output image pixels that map to an odd scan line above and an even scan line below are interpolated vertically. Output image pixels that map to an even scan line above and an odd scan line below are replicated vertically.

### 38.3.7 RGB/YUV444 Image Scaling

For all RGB formats, the RGB pixels are converted up to RGB888 with 8 bits per each color component.

Then each color component is passed to the scaling engine and each component is treated in the same manor. The RGB scaling operation is the same as for the Y scaling operation described in the preceding sections. Also, YUV444 contains a byte for each color plane at each pixel location, so all three color components are scaled in the same manor.

### 38.3.8 Color Space Conversion (CSC)

There are two modules in the PXP to convert pixels between color spaces. They are referred to as CSC1 and CSC2 (for lack of a better naming convention).

CSC1 exists after the scaling unit and is dedicated to converting from YUV to RGB. CSC2 is a full duplex color space converter in that it can convert into either RGB or YUV (or YCbCr) color spaces depending on the desired output pixel format. All coefficients are programmed as two's complement numbers and both CSC units can be bypassed if CSC is not desired at either position of these CSC units in the pixel data path.

### 38.3.9 CSC1 Operation

The CSC1 module receives scaled YUV/YCbCr444 pixels from the scale engine and converts the pixels to the RGB888 color space only if CSC1 is enabled.

The CSC1 module will convert only to the RGB color space and it can be bypassed to allow YUV pixels through the data path. These pixels are loaded into the pixel FIFO for processing by subsequent modules in the pixel data path.

The following equations are used to perform YUV/YCbCr → RGB conversion. The constants will be stored in the PXP control registers as two's complement values to allow flexibility in the implementation and to allow for differences in the video encode and decode operations. In addition, this provides a software mechanism to manipulate brightness or contrast.

$$R = C0(Y + Yoffset) + C1(V + UVoffset)$$

$$G = C0(Y + Yoffset) + C3(U + UVoffset) + C2(V + UVoffset)$$

$$B = C0(Y + Yoffset) + C4(U + UVoffset)$$

Note: In the equations above, U and V are synonymous with Cb and Cr in regards to the color space format of the source frame buffer.

Saturation of each color channel is checked and corrected for excursions outside the nominal YUV/YCbCr color spaces. Overflow for the three channels are saturated at 0x255 and underflow is saturated at 0x00.

The table below indicates the expected coefficients for YUV and YCbCr modes of operation:

Coefficient	YUV	YCbCr
Yoffset	0x000	0x1F0 (-16)
UVoffset	0x000	0x180 (-128)
C0	0x100 (1.00)	0x12A (1.164)
C1	0x123 (1.140)	0x198 (1.596)
C2	0x76B (-0.581)	0x730 (-0.813)
C3	0x79B (-0.394)	0x79C (-0.392)
C4	0x208 (2.032)	0x204 (2.017)

### 38.3.10 YUV versus YCbCr Support

By default, the PXP color space coefficients are set to support the conversion of YUV data to RGB data.

If YCbCr input is present, software must change the coefficient registers appropriately (see the register definitions for values). Software must also set the YCBCR\_MODE bit in the COEFF0 register to ensure proper conversion of YUV versus YCBCR data.

### 38.3.11 CSC2 operation

The CSC2 module receives pixels in any color space and can convert the pixels into any of RGB, YUV, or YCbCr color spaces.

All coefficients are programmable and in the two's complement notation. The output pixels are passed onto the LUT and rotation engine for further processing.

The following equations indicate the CSC2 modules ALU architecture.

Selecting RGB output in REG\_CSC2\_CTRL[CSC\_MODE] configures the ALU in the following manor:

$$R = A1(Y-D1) + A2(U-D2) + A3(V-D3)$$

$$G = B1(Y-D1) + B2(U-D2) + B3(V-D3)$$

$$B = C1(Y-D1) + C2(U-D2) + C3(V-D3)$$

Selecting YUV output configures the ALU in the alternate manor:

$$Y = A1*R + A2*G + A3*B + D1$$

$$U = B1*R + B2*G + B3*B + D2$$

$$V = C1*R + C2*G + C3*B + D3$$

Saturation of each color channel is checked and corrected for excursions outside the nominal color space. Overflow for the three channels are saturated at 0x255 and underflow is saturated at 0x00.

### 38.3.12 Alpha Blending/Color Key

Regardless of pixel input format, the PS and AS pixels are normalized to 32-bits, organized as one alpha and three data bytes.

Alpha blending occurs in the RGB space, if blending is required, PS pixels should be converted to RGB space. If no alpha blending is required, then YUV pixels can bypass the alpha blending ALU without color space conversion.

All pixels are processed by the pixel ALU, but the ALU operations can be disabled to achieve pixel pass through for either PS or AS source pixels.

### 38.3.13 Alpha Blend

The alpha value for an individual pixel represents a mathematical weighting factor applied to the AS pixel.

An alpha value of 0x00 corresponds to a transparent pixel and a value of 0xFF corresponds to an opaque pixel.

The effective alpha value for an AS pixel is determined by the REG\_AS\_CTRL[ALPHA] and REG\_AS\_CTRL[ALPHA\_CTRL] register fields. If

REG\_AS\_CTRL[ALPHA\_CTRL] = ALPHA\_OVERRIDE, the alpha value for the pixel is taken from the REG\_AS\_CTRL[ALPHA]. This can be useful for applying a constant alpha to an entire image or for image formats that don't include an alpha value. If REG\_AS\_CTRL[ALPHA\_CTRL] = ALPHA\_MULTIPLY, the pixel's alpha value will be multiplied by the pixel's ALPHA value in order to allow scaling of the pixel's alpha or to provide better control for pixel formats such as RGB1555, which only contains a single bit of alpha.

For each color channel, the equation used to blend two source pixels is defined below:

$Gá$  = PIO programmed global alpha (8-bit value).

$Eá$  = Embedded alpha associated with AS pixel.

$$á = Gá * Eá + 0x80$$

The result for the red channel as an example:

$$R[7:0] = (á * PS.r) + ((1 - á) * AS.r)$$

When  $á$  is 0xff, the PS pixel will not be blended with the AS pixel, but PS will be passed as the output pixel and will not be blended with AS. In this case, AS will be discarded. Likewise, if  $á$  is 0x00 for a given pixel, PS will be loaded as the output pixel.

REG\_AS\_CTRL[ALPHA\_INVERT] provides the option to invert the final alpha value. This essentially inverts the effect the alpha value has on the AS and PS blending operation.

### 38.3.14 Color Key

The color key function is provided to create transparent effects on the output pixel.

Color keying is applied on the input pixels after they are converted to 8-bits for each red, green, and blue color channels (color keys are not applied directly to 16-bit pixel formats but to their corresponding 24-bit representation). A color key range is programmable for both PS and AS pixels. If the PS 24-bit pixel is within the PS color key range, then AS is passed through the pixel pipeline. In this case, alpha blending does NOT occur.

Conversely, if PS is within the AS color key range, then PS is passed via the PXP data pipeline. If both PS and AS color key tests pass, then the back ground color register is passed onto following PXP processing components in the pipeline.

The condition for color keying to be satisfied is:

$$CK0.r.low \leq PS.r \leq CK0.r.high$$

$$CK0.g.low \leq PS.g \leq CK0.g.high$$

$$CK0.b.low \leq PS.b \leq CK0.b.high$$

For example, if the "red" 8-bit value for the PS pixel (or PS.r) is between the color key low and high values (CK0.r.l and CK0.r.h), the condition is true for the red color plane. When ALL three color planes meet this condition, then only the PS pixel is loaded into the output register.

To disable color keying, program the low color key register value to 0xff and the high value to 0x00. This will guarantee that the color key range test will never be true.

### 38.3.15 LUT

The lookup table (LUT) is used to modify pixels in a manner that is not linear and that cannot be achieved by the color space conversion modules.

Nonlinear response to the input pixels can be achieved based on how the lookup table is programmed.

Programming of the direct access LUT table can be facilitated by single PIO register writes or DMA access. For efficient loading of the LUT, DMA access should be used.

### 38.3.16 Lookup Modes

The LUT has four lookup modes. The lookup modes determine how the `src_pixel` is used to address the LUT memory.

The four lookup modes are:

1. `DIRECT_Y8`
2. `DIRECT_RGB444`
3. `DIRECT_RGB454`
4. `CACHE_RGB565`

The `DIRECT` modes access the LUT memory as a monolithic SRAM. The `CACHE_RGB565` will access the memory as a 2-way set associative cache.

### 38.3.17 `DIRECT_Y8`

`DIRECT_Y8` is used for a 256-byte lookup. In `DIRECT_Y8`, the most significant byte of the pixel is used to address the LUT entry.

This byte reflects the Y/R channel of the pixel data path. Luma, or monochrome, transformations are possible with this lookup mode. The address is generated as: `src_pixel[23:16]`. In `DIRECT_Y8` operation, the memory is byte addressable.

### 38.3.18 `DIRECT_RGB444`

`DIRECT_RGB444` is used for a 8KB (4K pixel) RGB444 to RGB565 lookup.

Pixel formats that are in the YUV color space at the position of the LUT in the PXP data path can also be converted. To take advantage of the full 16KB memory, the `REG_LUT_CTRL[SEL_8KB]` bit can be used to select the upper or lower 8KB memory, thus facilitating the use of 2 separate 444 LUT tables. In `DIRECT_RGB444`, the `src_pixel` is RGB/YUV[23:0] data is used to generate the lookup address. The address is generated as: `{R/Y[23:20],G/U[15:12],B/V[7:4]}`. In `DIRECT_RGB444`, the memory is pixel (2 byte) addressable.

### 38.3.19 `DIRECT_RGB454`

`DIRECT_RGB454` is used for a 16KB (8K pixel) RGB454 to RGB565 lookup.

Pixel formats that are in the YUV color space at the position of the LUT in the PXP data path can also be converted. In DIRECT\_RGB454, the src\_pixel is RGB/YUV[23:0] data is used to generate the lookup address. The address is generated as: {R/Y[23:20],G/U[15:11],B/V[7:4]}. In DIRECT\_RGB454, the memory is pixel (2 byte) addressable.

### 38.3.20 CACHE\_RGB565

The CACHE\_RGB565 lookup is used for a 128KB (65K pixel) RGB/YUV565 to RGB/YUV565 lookup.

The 128KB memory requirement is too costly from an area perspective to implement a complete lookup table in the LUT's on chip memory. For this reason, a LRU (least recently used) 16KB 2-way set associative cache has been implemented to reference the full 128KB lookup table stored in external memory.

The 2-way set associative cache is organized in the following way:

- 16KB total data storage
- 512 entries split between 256 ways
- 6 pixels/entry cache line

Cache efficiency is very critical. For a cache miss, the PXP will be stalled until the cache line can be filled. For a 32 bit DDR memory interface, the latency can be calculated as follows:

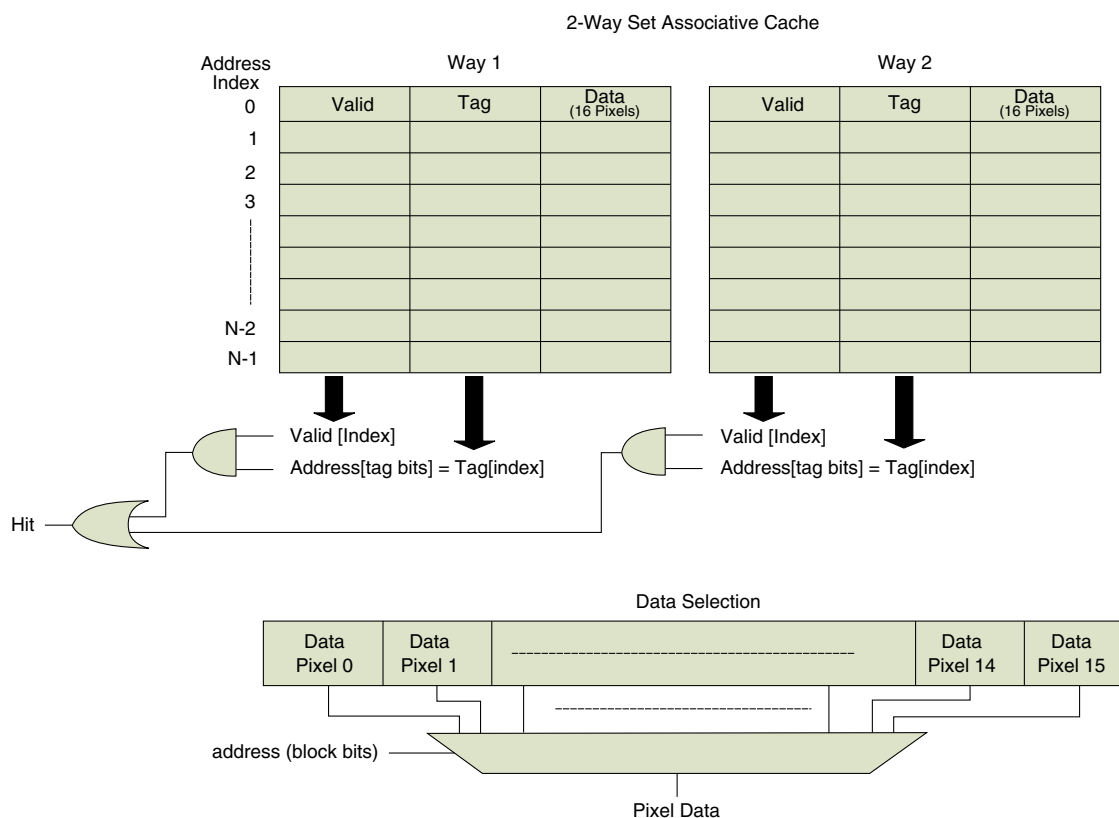

# cycles latency for read command through DDR controller + CAS Latency + # burst cycles for read data to be returned + # cycles latency for data through DDR controller to LUT + 1 cycle for cache access of new data

The src\_pixel is RGB[23:0] data used to generate the lookup address. To improve the cache efficiency the RGB/YUV565 address and the lookup table must be formatted in the following way:

Address:  $A[15:0] = R_7G_7G_6B_7 R_6G_5B_6 R_5G_4B_5 R_4G_3B_4 R_3G_2B_3$

The address is organized as follows:

- A[15:12] tag address, used to compare a hit between cache ways
- A[11:4] index address, used to select cache set (i.e. row of memory)
- A[3:0] block address, used to select Pixel in the cache line

**Figure 38-9. 2-Way Set Associative Cache and Data Selection**

### 38.3.21 Output Modes

The LUT has three output modes for color space conversion.

1. Y8
2. RGBW4444CFA
3. RGB888

### 38.3.22 Y8

With `out_mode` set to Y8, in conjunction with `DIRECT_Y8` lookup mode, the intended operation is Gamma Correction.

Only the third byte is processed by the lookup table. The third byte is represented by the Y value or the R value in the data path since pixel data is either YUV[23:0] or RGB[23:0] where the Y or R byte encompass bits [23:16] respectfully. So, bits 15:0 are

always bypassed and left unchanged. Currently, the LUT is intended to process Y data when any YUV, Y8, or Y4 output pixel formats are selected. However, this resource can be enabled and used for any conceivable purpose.

Note: When the DIRECT\_RGB444, DIRECT\_RGB454 or CACHE\_RGB565 lookup mode is selected in conjunction with the Y8 output mode the low order byte of the two bytes read from the LUT memory will be used as the Gama Correction value.

### 38.3.23 RGBW4444CFA

With REG\_LUT\_CTRL[OUT\_MODE] set to RGBW4444CFA, the REG\_CFA[DATA] is used to select one nibble from the LUT 16 bit output value.

The LUT memory lookup will contain a RGBW4444 value. The REG\_CFA[DATA] will select the R,G,B or W nibble as the pixel value to present to the PXP data path based on the matrix defined by the REG\_CFA[DATA] register. The 4 bit value is presented in the Y, or third byte lane, of the PXP data path. The final pixel transferred to the next PXP stage is {CFA[3:0],CFA[3:0],LUT[15:0]}

#### 38.3.23.1 CFA Correction

The 32-bit REG\_\_CFA[DATA] register is used to encode 16 CFA correction values.

The CFA correction values are encoded as follows:

- 00 selects R
- 01 selects G
- 10 selects B
- 11 selects W

The CFA correction uses 4x4 block processing. Figure 5; CFA mapping translation shows how CFA 4x4 blocks will iterate over the PXP's 8x8 or 16x16 pixel block being processed:

Figure 38-10. CFA mapping translation

### 38.3.24 RGB888

With `out_mode` set to RGB888, the memory output data is interpolated from RGB565 to RGB888.

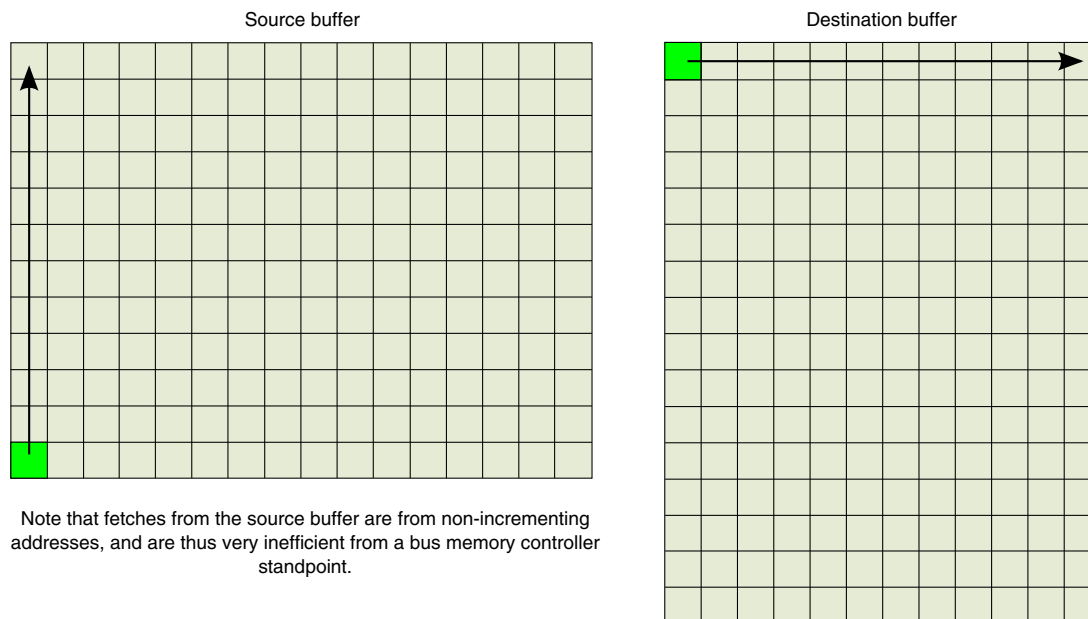

The RGB[23:0] data is formatted as follows: R[7:3]R[7:5],G[7:2]G[7:6],B[7:3]B[7:5].

### 38.3.25 Rotation

There is a single rotation resource integrated into the PXP. The location of this resource within the PXP data path is programmable. >Rotation can occur after compositing the AS and PS buffers in the output stage.

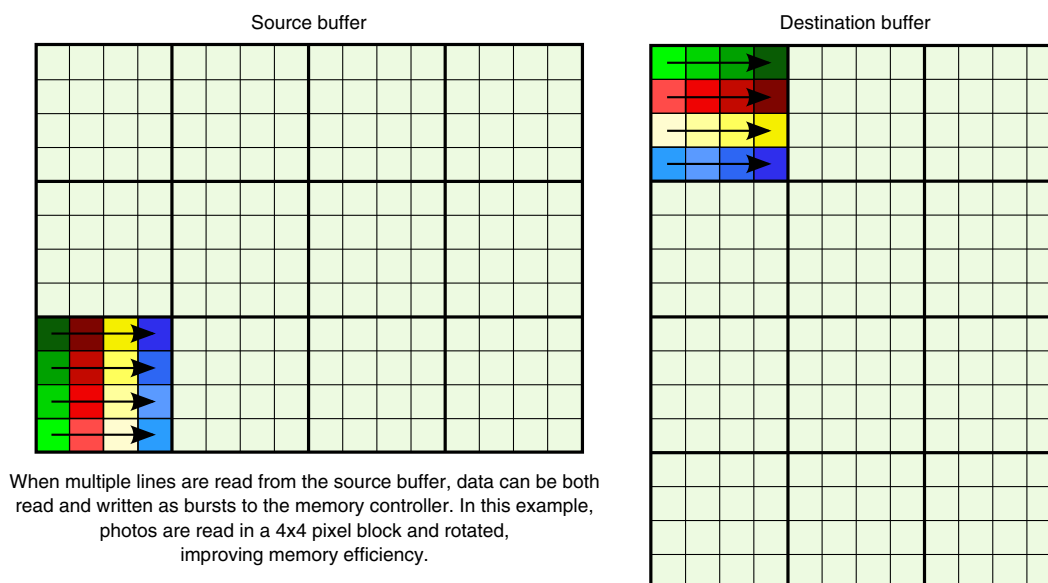

As an alternative configuration, the PS buffer can be rotated and later composited with the AS surface that is not rotated. There is a single configuration bit that provides the configuration of where rotation is implemented within the PXP.

To rotate graphics, the hardware must read pixels in one direction across a frame buffer and write them in an alternate orientation. For the 90 and 270 degree cases, this means that lines of pixels must either be read or written vertically in a frame buffer.

**Figure 38-11. Rotation Read and Write**

In order to rotate efficiently, multiple columns must be rotated to enable the engine to both fetch and store bursts of pixels, thus improving memory performance. The simplest method of doing this is to operate on square blocks of pixels. To rotate the image, each sub-block of pixels must be rotated by the required rotation angle.

**Figure 38-12. Rotated Sub-blocks**

To manage the rotation process, the source image can be broken into a grid of sub-blocks that have coordinates as shown in the diagram below. In addition to rotating the sub-block, each block must be translated to a new coordinate location. For each of the rotation angles (0, 90, 180, 270), it is possible to define a simple algorithm for computing the new translated grid address. The hardware must then simply compute the memory address from the base grid address for both load and store operations.

**Figure 38-13. Grid of Sub-Blocks with Coordinates**

In order to balance the requirements of reasonable burst sizes to the memory controller as well as keep the hardware storage requirements to a minimum, the blending/rotation engine will operate on either 8x8 or 16x16 pixel blocks.

**IMPORTANT NOTE:** An important artifact of the PXP is when rotating a source image and the output is NOT divisible by the block size selected. The output engine essentially truncates any output pixels after the desired number of pixels has been written. Since the output buffer is written as a horizontal row of blocks, the incorrect pixels could be truncated and the final output image can look shifted. In the case where the block size is programmed to 8x8, and the output size that is programmed is 12x12, then there is a remainder of 4 pixels that will be truncated in either the X and/or Y axis when the PXP operation is complete. The output will be shifted by 4 pixels in this example. To compensate for this, the source base address needs to be adjusted so the correct pixels get truncated and the image does not look shifted. In this example, with 90 degrees of rotation, the PS base address should be adjusted by 4 times the actual PS base address - (4\*pitch).

### 38.3.26 Output Buffer

The output buffer engine accepts data from the PXP pixel pipeline and issues requests to transfer the output pixels to external DRAM or the internal SRAM double buffer row of blocks.

### 38.3.27 Address calculator

Each of the blocks will manage its own fetch address using a common address calculator block that computes real addresses from a base address and relative block offset from the base.

Each block will then perform the multiple line fetches (or stores) required to perform the operation. This hides all the address buffer computations from the processing blocks and allows each block to simply track the coordinate of the block it is working on.

### 38.3.28 Block size selection

The PXP can be configured to process blocks that are either 8x8 pixels or 16x16 pixels with the REG\_CTRL[BLOCK\_SIZE] control bit.

When selecting a 16x16 pixel block size, the accesses to fetch AS and PS images and write the final frame buffer are more efficient since twice as much data is requested and processed per memory request.

When optimizing the system for memory bandwidth and image processing time, configure the PXP to process 16x16 pixel blocks.

### 38.3.29 Interlaced Video Support

The PXP has some minimal ability to generate interlaced video content from a progressive source. There two available options, based on the bandwidth requirements and how software is managing video frames.

The PXP can either interlace on the input side (by reading every other line of input data) or on the output side (by writing the individual lines of video into two separate fields). Generally, output interleaving should be used since it is the most flexible mode (it allows scaling and full overlay support) and it only requires a single pass of the PXP to generate two separate output fields.

Input interleaving can be beneficial in cases where the PXP is running at 60fps, since it requires fewer fetches to produce the output data. There is no direct hardware support for input interleaving, in that, there is no configuration bit that can be set to alter how the PXP processes a frame for input interleaving. Input interleaving is achieved by simply setting the source frame buffer pitch value to twice the value it would normally be set to for the equivalent progressive frame. The output parameters also need to be consistent with the desired processing effect. For example, the vertical resolution would be set to account for the reduced resolution to process the interlaced input buffers.

### 38.3.30 LCDIF Handshake

The PXP and LCDIF support a mode where the internal SRAM can be used for the frame buffer to minimize external memory bandwidth required.

This is accomplished by creating two buffers in SRAM, a double buffer row of blocks, where each correspond to 8/16-lines of the frame buffer. The buffers must be consecutive and allocated as a single block of data.

**Figure 38-14. Buffer in OCRAM**

The storage required can be calculated for an 8x8 block size as

- $\text{storage} = 16 (\text{lines}) * \text{rotated\_row\_length} * \text{pixel\_size}$

and for 16x16 block size as

- $\text{storage} = 32 (\text{lines}) * \text{rotated\_row\_length} * \text{pixel\_size}$

where  $\text{pixel\_size} = 4$  for 32bpp or 2 for 16bpp modes. The following table lists the storage requirements for common image sizes using 8x8 block size:

Image Size	Storage (16bpp)	Storage (24bpp)	Storage (32bpp)
320x240 (QVGA) - 0/180 rotation	10KB	15KB	20KB
320x240 (QVGA) - 90/270 rotation	7.5KB	11.5KB	15KB
640x480 (VGA) - 0/180 rotation	20KB	30KB	40KB

*Table continues on the next page...*

640x480 (VGA) - 90/270 rotation

15KB

22.5KB

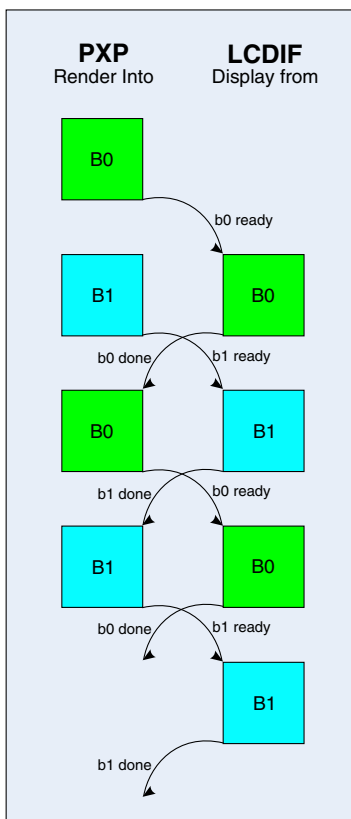

30KB

The following diagram shows how the minimal rotation buffer would be organized. As the engine and LCD progress down the image, they continually swap roles of filling and emptying each eight-line buffer.

**Figure 38-15. Minimal Rotation Buffer Organization**

When this mode is enabled, the PXP will process one row of pixel blocks and write the results to the first SRAM buffer (buffer 0). The PXP will then alternate between writing subsequent rows to buffer 0 and buffer 1. After the PXP generates the data for one buffer, the LCDIF will begin reading that buffer and send the contents to the display device. Once the LCDIF finishes reading a buffer, it will start displaying from the other buffer while the PXP continues filling the previously processed buffer.

**Figure 38-16. PXP and LCDIF Buffer Sharing**

To accomplish the buffer sharing, the PXP and LCDIF will maintain buffer status using a pair of handshake signals. When a buffer is filled by the PXP, it will assert the `pxp_lcdif_bx_ready` (where x is 0 or 1) signal to indicate to the LCDIF that the buffer has valid data. The LCDIF will then release the buffer by asserting the `lcdif_pxp_bx_done` signal.

The basic protocol is shown in the diagram below:

**Figure 38-17. Buffer Sharing Protocol**

The PXP will continue to assert the `bx_ready` signal until the corresponding `bx_done` signal is sampled high for one clock cycle. It will then deassert the `bn_ready` until the next time the buffer has been filled. After the PXP samples the `bx_done` signal asserted, it is free to begin filling the buffer with the next block size lines of display data. If a buffer has not been released when the PXP is ready to process data for that buffer, it will suspend rendering operations until the buffer has been released by the LCDIF.

### 38.3.31 LCDIF Abort

When the memory subsystem is not loaded, the PXP should be able to render the buffers faster than the LCDIF can drain the buffers.

It is possible under some scenarios (high LCDIF output rates with high memory latency) that the PXP may not be able to keep up with the LCDIF, even in the SRAM mode of operation. When this happens, the LCDIF will signal that it has completed one of the buffers before the other has been rendered by the PXP. This condition will be detected by the PXP's control logic as an "LCDIF Abort", which will cause the PXP to abort processing in the current row and proceed to the following row. It will acknowledge the abort to the LCDIF by raising the `buffer_ready` signal for the current buffer to enable the LCDIF to begin displaying the partially-filled buffer. While an abort will create artifacts in the video display, it does minimize the artifacts by limiting them to the remaining pixels blocks in the current row versus ruining the entire frame buffer.

Figure 38-18. LCDIF Abort

### 38.3.32 Theory of Operation

The PXP can be used to accelerate graphics operations by offloading graphics processing from the processor. The block can perform alpha blending and color key substitution on two RGB graphics buffers.

The PXP is organized as having a processed surface (PS) and an alpha surface (AS) that can be blended with the processed surface. There are no restrictions on the location of the AS or PS within the output surface (OS). As the PXP processes NxN blocks, operations

are performed on a pixel by pixel basis. The AS and PS pixels are alpha blended, color keyed, process by CSC and LUT resources as individual pixel components. This allows efficient block processing with supporting arbitrary alignment for both the AS and PS surfaces. The resulting pixel block is then written to the corresponding block in the output buffer.

### 38.3.33 Pixel Handling

All pixels are internally represented as 24-bit values regardless of input or output pixel formats.

The pixels get converted in the AS and PS buffer engines to 24-bit pixel values.. There is also an 8-bit alpha value at stages up to the alpha blender within the PXP for blending within the RGB color space. Compositing of AS and PS images can only occur in the RGB color space. If compositing is not required, then YUV pixels can be transferred and processed at all PXP pixel resource components.. The color orientation of pixels within the PXP can be controlled by the CSC1, CSC2, and LUT resources.

For RGB, input pixels are converted into 24-bit pixel values using the following rules:

1. 32-bit ARGB8888 pixels are read directly with no conversion for both the AS and PS.
2. 32-bit RGB888 pixels are assumed to have an alpha value of 0xFF (full opaque).
3. 6-bit RGB565 and RGB555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of 0xFF (opaque). The expansion process replicates the upper pixel bits into the lower pixel bits (for instance a 16-bit RGB555 triplet of 0x1F/0x10/0x07 would be expanded to 0xFF/0x84/0x39).
4. 16-bit RGB1555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of either 0x00 or 0xFF, based on the 1-bit alpha value in the pixel. The ALPHA\_MULTIPLY function is useful in this scenario to allow scaling of the opaque pixels to a semi-transparent value.

Alpha values can be passed through the entire PXP data path and output in ARGB888 and ARGB555 pixel modes. Also, output pixels can be assigned an alpha value using the REG\_OUT\_CTRL[ALPHA] register. 16-bit pixels values are formed from the most significant bits of the 24-bit pixel values.

When YUV/YCbCr output formats are selected, all pixels are internally represented as either RGB or YUV pixels values. The CSC2 or LUT can convert internal RGB/YUV pixels into the correct output format. In this way, any PS color space can be blended with AS RGB pixels and output in any color space.

### 38.3.34 Output Buffer Composition

The output buffer will be rendered by composing each pixel block from the associated PS and AS buffers.

The AS pixel buffer can be blended or color-keyed with the associated data from the PS buffer (either the PS image pixels or REG\_PS\_BACKGROUND register based on PS programmed coordinates).

Figure 38-19. Output Buffer Composition

### 38.3.35 PS Image Processing

As the PXP processes image buffers, it iterates over the output buffer by fetching the corresponding input buffer blocks and processing the pixels embedded in these.

### 38.3.36 Letterboxing

At each pixel coordinate, the control logic determines if the PS pixel (argument also applies to AS pixels) will be used in rendering the output pixel.

This is determined by checking the output pixel's coordinates against the REG\_OUT\_PS\_ULC and REG\_OUT\_PS\_LRC (ULC and LRC in short) register contents. For pixels outside this region, the PS pixel will be loaded with the pixel value from REG\_PS\_BACKGROUND, which can be used to effectively control the letterboxing color. There are no block size or block boundary restrictions when setting the ULC or LRC for either the AS or PS. The only restriction is that the ULC and LRC are within the OUT LRC extents.

**Figure 38-20. OUT Buffer**

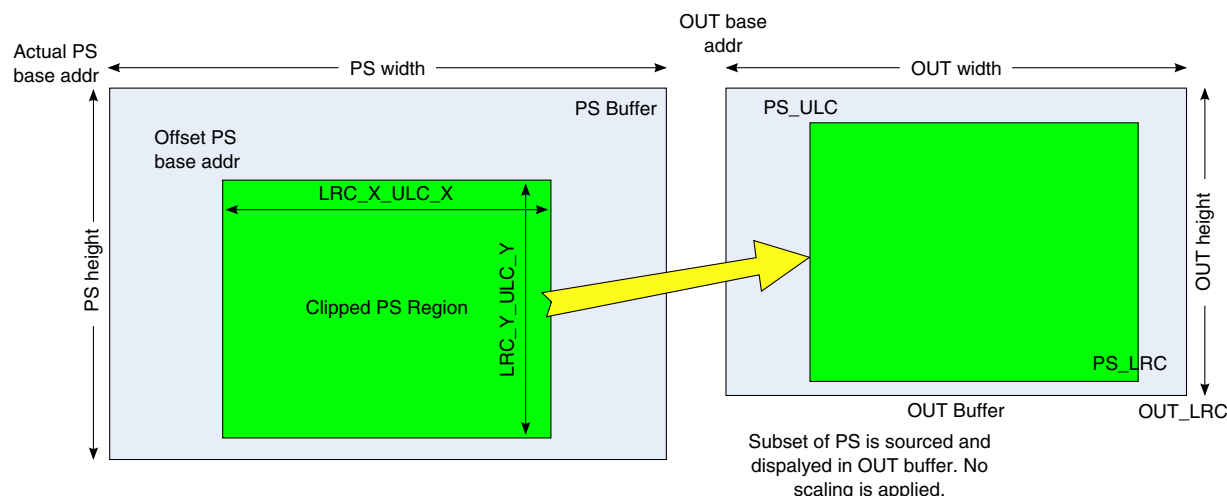

### 38.3.37 Clipping source images

A subset of the PS buffer can be used in rendering the output buffer. The PXP\_PS\_BUF register can indicate an offset into the PS buffer that will be used for display within the OUTPUT buffer.

The pixel at the address defined in the PXP\_PS\_BUF register will be the pixel that is displayed at the pixel coordinate indicated by PXP\_OUT\_PS\_ULC within the output buffer. Essentially, the PXP\_PS\_BUF register can be used to establish an offset into the PS buffer thus clipping all PS buffer pixels that are at a lower address. The PXP\_PS\_PITCH will always indicate the number of bytes that are vertically adjacent in

the PS buffer. The settings in the PXP\_PS\_BUF, PXP\_OUT\_PS\_ULC, and PXP\_OUT\_PS\_LRC will determine the subset of the PS buffer, or clipped PS source buffer, that will be used in the output buffer.

It is important to note that when scaling the PS buffer, the coordinates of the PS buffer within the output buffer need to be consistent with the scaling factors and original PS buffer size.

**Figure 38-21. PS Buffer Scaling**

When sourcing a subset of the PS image, it should fall completely within the PS buffer to avoid displaying incorrect data. The following conditions should be met:

$$x\_base\_addr\_offset + x\_scale * (LRC\_X - ULC\_X) \leq PS\_pitch$$

$$y\_base\_addr\_offset + y\_scale * (LRC\_Y - ULC\_Y) \leq PS\_size$$

The PXP hardware does not check for these conditions and will render the image as programmed. The following case could indicate invalid programming parameters for the PXP:

Figure 38-22. Example with Invalid Parameters

### 38.3.38 Color Key Processing

Pixels may be made transparent to the corresponding AS by using the PS color key registers.

If a PS pixel matches the range specified by the REG\_PS\_COLORKEYLOW and REG\_PS\_COLORKEYHIGH registers, the pixel from the associated AS will be displayed. If no AS is present for the pixel, a black pixel will be generated since the default AS pixel is 0x00000000 (transparent black pixel).

The most common use for this is when a bitmap does not support an alpha-field or for applications such as "green screen" where an image is substituted for a solid background color .

**Figure 38-23. The PS image (player) and AS image (stadium)**

The green portion of the background image can be color keyed to display the contents of the AS buffer for locations that match the color range. For this example, the color range is:

PS Colorkey:  $00 < R < 80$   $70 < G < ff$   $00 < B < 80$

The resulting image becomes:

**Figure 38-24. Resulting Image**

### 38.3.39 In Place Processing (PS buffer is destination buffer)

The PXP also has the ability to process an image and write the resulting buffer back to the original PS buffer. This is referred to as "in place" rendering.

This could be useful for basic blit operations into the PS buffer. IN\_PLACE operations are achieved by programming the OUT base address to the pixel location in the PS buffer that marks the upper left pixel of the update region. The actual region that is updated should be indicated by programming the ULC = (0,0) and the LRC = (X,Y). The region bounded by the coordinates will be updated, and the rest of the PS buffer will not be modified.

### 38.3.40 Alpha Surface (AS) Processing

The AS surface has a complete set of registers that determines how the AS effects the final OUT surface.

Most of the registers that exist for the PS surface also are defined for the AS surface where applicable. This is provided to replicate the SW interface for each PS and AS processes.

### 38.3.41 Alpha Handling

Alpha values in the AS are embedded in the source image pixels. For AS pixel formats that do not support an alpha value, the pixel is assigned an alpha value of 0xFF (opaque).

This can be modified by the AS control by setting either the ALPHA\_MULTIPLY or ALPHA\_OVERRIDE bit in the associated AS\_CTRL register. If ALPHA\_MULTIPLY is enabled, the 8-bit ALPHA value from the AS\_CTRL register is multiplied by the source alpha before blending with the PS image. If the ALPHA\_OVERRIDE bit is set, the 8-bit ALPHA value is simply substituted for the pixel.

### 38.3.42 Color Key Processing (AS\_CTRL)

The AS\_CTRL register also contains an ENABLE\_COLORKEY bit that can be used to enable or disable color key substitution for the AS.

When enabled, the pixel values are compared to the ASCOLORKEYLOW and ASCOLORKEYHIGH registers to determine if a match has occurred. When an AS pixel matches the color key range, the pixel from the AS image is considered transparent and the corresponding PS pixel is rendered. If both the PS and AS pixels match their corresponding color key ranges, the AS pixel is displayed unmodified.

AS color keys are handled in a manner similar to PS color keys. The same images used in the PS color key example could be used with the images swapped. In this case, matches on the AS image to the ASCOLORKEY register would display the PS pixels.

## 38.4 Output Image Processing

Several PXP options affect the resulting output image.

### 38.4.1 Output Image Size

The PXP generates an output image in the resolution programmed by the REG\_OUT\_LRC. As the PXP processes pixels, it iterates over the NxN blocks (in output scan-block order) based on the final image resolution.

### 38.4.2 Output Format

The result of PXP operations are written to the buffer pointed to by the REG\_OUT\_BUF/REG\_OUT\_BUF2 registers. The pixel format is controlled by the REG\_OUT\_CTRL[FORMAT] bit-field.

32-bit pixels are formed directly from the internal 24-bit representations and 16-bit pixel formats are generated by truncating the internal 24-bit values to the appropriate number of bits. For formats supporting an alpha value, the PXP assigns the alpha using the 8-bit value in the REG\_OUT\_CTRL[ALPHA] field. For ARGB1555, the most significant alpha bit is appended to the output pixel. Also, for ARGB4444, the most significant nibble is appended to the output pixel. Single and dual buffer YUV output formats are also available. Since each pixel in the data path is represented by a full YUV444 24bpp value, decimation reduces the output in cases of YUV422/420 output formats.

### 38.4.3 Rotation/Flip operations

The PXP supports four rotation angles in conjunction with vertical and horizontal flip options. The flip operations effectively take place before the rotation.

Rotations of 0, 90, 180, and 270 degrees are supported and any combination of rotation and flip are supported. There is no performance difference between any of these modes of operation.

## 38.5 Queuing PXP transactions

The PXP supports a primitive ability to queue up one operation while the current operation is running. This is enabled through the use of the REG\_NEXT register.

When this register is written, it enables the PXP to reload its current register contents with the data found at the location pointed to by this address when it completes processing of the current frame. This feature may be useful in helping to reduce the interrupt latency in servicing the PXP, especially in cases where the PXP and LCDIF are using the on-chip SRAM buffer handshake (since the PXP must begin generating next frame data immediately).

If the PXP is idle when the REG\_NEXT register is written, the PXP treats this as an indication that it should immediately load the values at the pointer and begin processing the frame. This ability should allow software to use the same routines when programming the PXP (so that the first frame doesn't differ from subsequent frames).

When loading values from the NEXT register, all registers in the PXP are reloaded. Some register loads have no effect

After writing the REG\_NEXT register, the PXP will set the REG\_NEXT[ENABLED] bit of the REG\_NEXT register to indicate that the next command has been queued. Software should first check the status of this bit to ensure that a previous command has not been enabled. Likewise, after programming the first frame in a sequence of frames, software should poll this bit until it is sampled logic 1'b0 before queuing the next operation.

The PXP will issue interrupts from frames as they complete, regardless of whether they were started by writing the control registers directly or using the REG\_NEXT register. When software receives an interrupt, it should check/clear the PXP's status register as normal, poll the REG\_PXP[ENABLED] bit, and then issue the next operation. A queued operation may be cancelled by issuing a CLEAR operation to the REG\_PXP[ENABLED] register bit. The SET and TOGGLE operations should never be used with this register.

## 38.6 Error Handling

The PXP does minimal checking on the control registers, so it is important that these are correctly specified. The PXP does monitor the bus transactions for errors and will report errors in the status register.

Upon receipt of a bus error, the PXP will set the ERROR interrupt and abort any further operations. Bus errors can be generated from any system access that results in an error response returned from the internal SIM Bus errors in the PXP are signaled as either a read or a write error, but do not indicate the failing address. Software may deduce the failing address from the current block status indicators.

### 38.6.1 Known PXP Limitations/Issues

The PXP has the following known limitations:

1. When using the NEXT register, the interrupt enable setting should remain the same for all frames. If not, the PXP will change the interrupt enable register value and possible cause the loss of an interrupt.
2. Rotations of 180/270 are not supported when performing LCD handshakes

## 38.7 PXP Memory Map/Register Definition

PXP Hardware Register Format Summary

**PXP memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
20F_0000	Control Register 0 (PXP_CTRL)	32	R/W	C000_0000h	<a href="#">38.7.1/2316</a>

### 38.7.1 Control Register 0 (PXP\_CTRL)

The CTRL register contains controls for the PXP module.

PXP\_CTRL: 0x000

PXP\_CTRL\_SET: 0x004

PXP\_CTRL\_CLR: 0x008

PXP\_CTRL\_TOG: 0x00C

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

#### EXAMPLE

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 20F\_0000h base + 0h offset = 20F\_0000h

PXP\_CTRL field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal PXP operation. Set this bit to one (default) to disable clocking with the PXP and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the PXP block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 RSVD4	Reserved, always set to zero.
28 EN_REPEAT	Enable the PXP to run continuously. When this bit is set, the PXP will repeat based on the current configuration register settings. If this bit is not set, the PXP will complete the process and enter the idle state ready to accept the next frame to be processed. This bit should be set when the LCDIF handshake mode is enabled so that the next frame is automatically generated for the next screen refresh cycle. If it not set and the handshake mode is enabled, the CPU will have to initiate the PXP for the next refresh cycle. When the PXP NEXT feature is used, it has priority over the REPEAT mode, in that the new register settings are fetched first, and then the next PXP operation will continue.
27–24 RSVD3	Reserved, always set to zero.
23 BLOCK_SIZE	Select the block size to process. 0x0 <b>8X8</b> — Process 8x8 pixel blocks. 0x1 <b>16X16</b> — Process 16x16 pixel blocks.
22 ROT_POS	This bit controls where rotation will occur in the PXP datapath. Setting this bit to 1'b0 will place the rotation resources at the output stage of the PXP data path. Image compositing will occur before pixels are processed for rotation. Setting this bit to a 1'b1 will place the rotation resources before image composition. Only the PS can be rotated in this configuration and AS will not be rotated.
21–12 RSVD1	Reserved, always set to zero.
11 VFLIP	Indicates that the output buffer should be flipped vertically (effect applied before rotation).
10 HFLIP	Indicates that the output buffer should be flipped horizontally (effect applied before rotation).

Table continues on the next page...

**PXP\_CTRL field descriptions (continued)**

Field	Description
9–8 ROTATE	Indicates the clockwise rotation to be applied at the output buffer. The rotation effect is defined as occurring after the FLIP_X and FLIP_Y permutation.  0x0 <b>ROT_0</b> — 0x1 <b>ROT_90</b> — 0x2 <b>ROT_180</b> — 0x3 <b>ROT_270</b> —
7–5 RSVD0	Reserved, always set to zero.
4 ENABLE_LCD_HANDSHAKE	Enable handshake with LCD controller. When this is set, the PXP will not process an entire framebuffer, but will instead process rows of NxN blocks in a double-buffer handshake with the LCDIF. This enables the use of the onboard SRAM for a partial frame buffer.
3 LUT_DMA_IRQ_ENABLE	LUT DMA interrupt enable. When set, the PXP will issue an interrupt when the LUT DMA has finished transferring data.
2 NEXT_IRQ_ENABLE	Next command interrupt enable. When set, the PXP will issue an interrupt when a queued command initiated by a write to the PXP_NEXT register has been loaded into the PXP's registers. This interrupt also indicates that a new command may now be queued.
1 IRQ_ENABLE	Interrupt enable. NOTE: When using the PXP_NEXT functionality to reprogram the PXP, the new value of this bit will be used and may therefore enable or disable an interrupt unintentionally.
0 ENABLE	Enables PXP operation with specified parameters. The ENABLE bit will remain set while the PXP is active and will be cleared once the current operation completes. Software should use the IRQ bit in the PXP_STAT when polling for PXP completion.

**38.7.2 Status Register (PXP\_STAT)**

The PXP Interrupt Status register provides interrupt status information.

PXP\_STAT: 0x010

PXP\_STAT\_SET: 0x014

PXP\_STAT\_CLR: 0x018

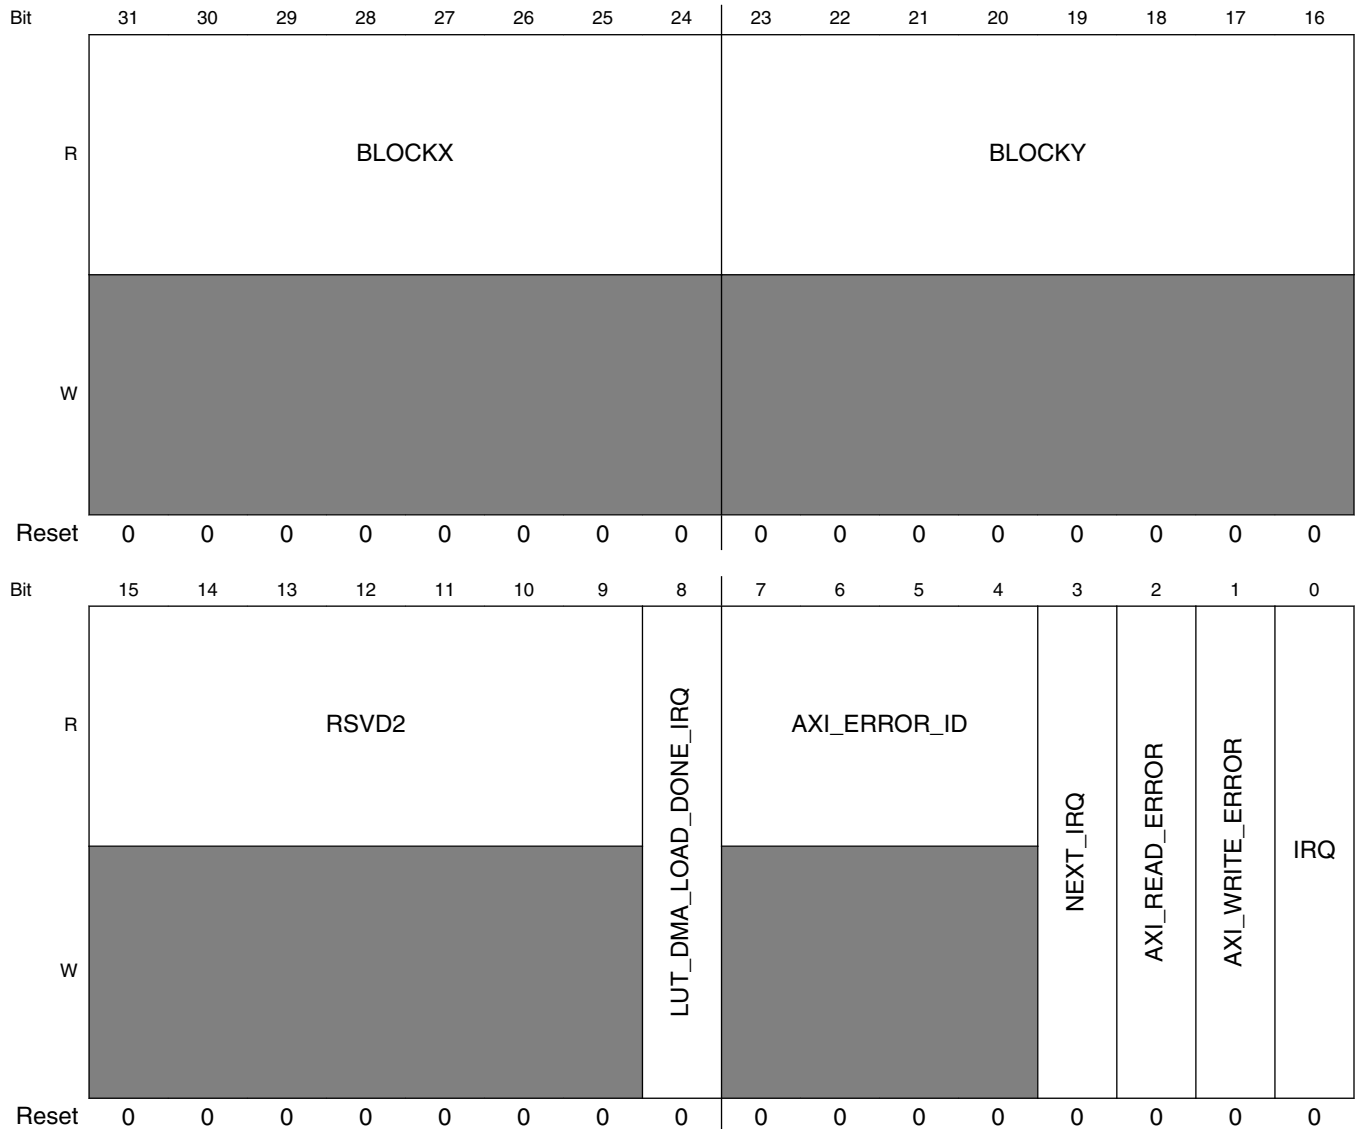

PXP\_STAT\_TOG: 0x01C

This register provides PXP interrupt status and the current X/Y block coordinate that is being processed.

**EXAMPLE**

```
PXP_STAT_CLR(BM_PXP_STAT_IRQ); // clear CSC interrupt
```

Address: 20F\_0000h base + 10h offset = 20F\_0010h

**PXP\_STAT field descriptions**

Field	Description
31–24 BLOCKX	Indicates the X coordinate of the block currently being rendered.
23–16 BLOCKY	Indicates the X coordinate of the block currently being rendered.
15–9 RSVD2	Reserved, always set to zero.
8 LUT_DMA_LOAD_DONE_IRQ	Indicates that the LUT DMA transfer has completed.
7–4 AXI_ERROR_ID	Indicates the AXI ID of the failing bus operation.

*Table continues on the next page...*

**PXP\_STAT field descriptions (continued)**

Field	Description
3 NEXT_IRQ	Indicates that a command issued with the "Next Command" functionality has been issued and that a new command may be initiated with a write to the PXP_NEXT register.
2 AXI_READ_ERROR	Indicates PXP encountered an AXI read error and processing has been terminated.
1 AXI_WRITE_ERROR	Indicates PXP encountered an AXI write error and processing has been terminated.
0 IRQ	Indicates current PXP interrupt status. The IRQ is routed through the pxp_irq when the IRQ_ENABLE bit in the control register is set.

**38.7.3 Output Buffer Control Register (PXP\_OUT\_CTRL)**

The OUT\_CTRL register contains controls for the Output Buffer.

PXP\_OUT\_CTRL: 0x020

PXP\_OUT\_CTRL\_SET: 0x024

PXP\_OUT\_CTRL\_CLR: 0x028

PXP\_OUT\_CTRL\_TOG: 0x02C

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

**EXAMPLE**

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 20F\_0000h base + 20h offset = 20F\_0020h

**PXP\_OUT\_CTRL field descriptions**

Field	Description
31–24 ALPHA	When generating an output buffer with an alpha component, the value in this field will be used when enabled to override the alpha passed through the pixel data pipeline.
23 ALPHA_OUTPUT	Indicates that alpha component in output buffer pixels should be overwritten by PXP_OUT_CTRL[ALPHA]. If 0, retain their alpha value from the computed alpha for that pixel.
22–10 RSVD1	Reserved, always set to zero.
9–8 INTERLACED_OUTPUT	Determines how the PXP writes it's output data. Output interlacing should not be used in conjunction with input interlacing. Splitting frames into fields is most efficient using output interlacing. 2-plane output formats AND interlaced output is NOT supported.  0x0 <b>PROGRESSIVE</b> — All data written in progressive format to the OUTBUF Pointer. 0x1 <b>FIELD0</b> — Interlaced output: only data for field 0 is written to the OUTBUF Pointer.

*Table continues on the next page...*

## PXP\_OUT\_CTRL field descriptions (continued)

Field	Description
0x2	<b>FIELD1</b> — Interlaced output: only data for field 1 is written to the OUTBUF2 Pointer.
0x3	<b>INTERLACED</b> — Interlaced output: data for field 0 is written to OUTBUF and data for field 1 is written to OUTBUF2.
7–5 RSVD0	Reserved, always set to zero.
4–0 FORMAT	Output framebuffer format. The UV byte lanes are synonymous with CbCr byte lanes for YUV output pixel formats. For example, the YUV2P420 format should be selected when the output is YCbCr 2-plane 420 output format.  0x0 <b>ARGB8888</b> — 32-bit pixels 0x4 <b>RGB888</b> — 32-bit pixels (unpacked 24-bit pixel in 32 bit DWORD.) 0x5 <b>RGB888P</b> — 24-bit pixels (packed 24-bit format) 0x8 <b>ARGB1555</b> — 16-bit pixels 0x9 <b>ARGB4444</b> — 16-bit pixels 0xC <b>RGB555</b> — 16-bit pixels 0xD <b>RGB444</b> — 16-bit pixels 0xE <b>RGB565</b> — 16-bit pixels 0x10 <b>YUV1P444</b> — 32-bit pixels (1-plane XYUV unpacked) 0x12 <b>UYVY1P422</b> — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes) 0x13 <b>VYUY1P422</b> — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes) 0x14 <b>Y8</b> — 8-bit monochrome pixels (1-plane Y luma output) 0x15 <b>Y4</b> — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation) 0x18 <b>YUV2P422</b> — 16-bit pixels (2-plane UV interleaved bytes) 0x19 <b>YUV2P420</b> — 16-bit pixels (2-plane UV) 0x1A <b>YVU2P422</b> — 16-bit pixels (2-plane VU interleaved bytes) 0x1B <b>YVU2P420</b> — 16-bit pixels (2-plane VU)

## 38.7.4 Output Frame Buffer Pointer (PXP\_OUT\_BUF)

Output Framebuffer Pointer. This register points to the beginning of the output frame buffer. This pointer is used for progressive format and field 0 when generating interlaced output.

This register is used by the logic to point to the current output location for the output frame buffer.

## EXAMPLE

```
PXP_OUT_BUF_WR( buffer );
```

Address: 20F\_0000h base + 30h offset = 20F\_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**PXP\_OUT\_BUF field descriptions**

Field	Description
31–0 ADDR	Current address pointer for the output frame buffer. The address can have any byte alignment. 64B alignment is recommended for optimal performance.

**38.7.5 Output Frame Buffer Pointer #2 (PXP\_OUT\_BUF2)**

Output Framebuffer Pointer #2. This register points to the beginning of the output frame buffer for either field 1 when generating interlaced output or for the UV buffer when in YUV 2-plane output modes. Both interlaced output AND 2-plane output modes are not supported in a single PXP operation. This register is NOT used as the pointer to the 2nd buffer when in LCDIF\_HANDSHAKE mode.

This register is used by the logic to point to the current output location for the field 1 or UV output frame buffer.

**EXAMPLE**

```
PXP_OUT_BUF_WR( field0 ); // buffer for interlaced field 0
PXP_OUT_BUF2_WR( field1 ); // buffer for interlaced field 1
```

Address: 20F\_0000h base + 40h offset = 20F\_0040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**PXP\_OUT\_BUF2 field descriptions**

Field	Description
31–0 ADDR	Current address pointer for the output frame buffer. The address can have any byte alignment. 64B alignment is recommended for optimal performance.

**38.7.6 Output Buffer Pitch (PXP\_OUT\_PITCH)**

This register contains the output buffer pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in output pixel address calculations.

**EXAMPLE**

## PXP Memory Map/Register Definition

```
PXP_OUT_PITCH_WR( 68 * 4 ); // The output buffer pitch is 68 pixels times 32 bits per pixel
```

Address: 20F\_0000h base + 50h offset = 20F\_0050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD																PITCH															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### PXP\_OUT\_PITCH field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
15–0 PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

## 38.7.7 Output Surface Lower Right Coordinate (PXP\_OUT\_LRC)

This register contains the size, or lower right coordinate, of the output buffer NOT rotated. It is implied that the upper left coordinate of the output surface is always [0,0]. When rotating the framebuffer, the PXP will automatically swap the X/Y, or WIDTH/HEIGHT, to accommodate the rotated size.

This register sets the size of the output frame buffer in pixels, not blocks. The frame buffer need not be a multiple of NxN pixels. Partial blocks will be written for output frame buffer sizes that are not divisible by N pixels in either dimension.

### EXAMPLE

```
PXP_OUT_LRC[X]=319; // set width of output frame buffer to 320 pixels
PXP_OUT_LRC[Y]=243; // set height of output frame buffer to 244 pixels which is not
divisible by block size N
```

```
PXP_OUT_LRC_WR( BF_PXP_OUT_LRC_X(319) | BF_PXP_OUT_LRC_Y(243) );
```

Address: 20F\_0000h base + 60h offset = 20F\_0060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD1								X							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0								Y							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PXP\_OUT\_LRC field descriptions**

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	Indicates number of horizontal PIXELS in the output surface (non-rotated). The output buffer pixel width minus 1 should be programmed. The image size is not required to be a multiple of 8 pixels. The PXP will clip the pixel output at this boundary.
15–14 RSVD0	Reserved, always set to zero.
13–0 Y	Indicates the number of vertical PIXELS in the output surface (non-rotated). The output buffer pixel height minus 1 should be programmed. The image size is not required to be a multiple of 8 pixels. The PXP will clip the pixel output at this boundary.

### 38.7.8 Processed Surface Upper Left Coordinate (PXP\_OUT\_PS\_ULC)

This register contains the upper left pixel coordinate for the Processed Surface in the OUTPUT buffer.

This register contains the upper left coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the PXP\_OUT\_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. If the value of the PXP\_OUT\_PS\_ULC is greater than the PXP\_OUT\_LRC, then no PS pixels will be fetched from memory, but only PXP\_PS\_BACKGROUND pixels will be processed by the PS engine. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the PXP\_OUT\_LRC extents will use the PS to render pixels into the output buffer.

#### EXAMPLE

```
PXP_OUT_PS_ULC_WR(0,0x0002_0002); // Processed Surface upper left coordinate at (X,Y) = 2,2. The PS surface will not effect pixels in the first and second row and column of the output buffer.
```

Address: 20F\_0000h base + 70h offset = 20F\_0070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD1		X													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0		Y													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PXP\_OUT\_PS\_ULC field descriptions**

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the upper left X-coordinate (in pixels) of the processed surface (PS) in the output buffer.
15–14 RSVD0	Reserved, always set to zero.
13–0 Y	This field indicates the upper left Y-coordinate (in pixels) of the processed surface in the output buffer.

### 38.7.9 Processed Surface Lower Right Coordinate (PXP\_OUT\_PS\_LRC)

This register contains the lower right extent for the Processed Surface in the OUTPUT buffer.

This register contains the lower right coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the PXP\_OUT\_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the PXP\_OUT\_LRC extents will use the PS to render pixels into the output buffer.

#### EXAMPLE

```
PXP_OUT_PS_ULC_WR(0,0x03FF_03FF); // With this UL/LR pair of pixel coordinates, only one
pixel at OUT[X,Y]=1023,1023 will use the PS to contribute to its value.
PXP_OUT_PS_LRC_WR(0,0x03FF_03FF);
```

Address: 20F\_0000h base + 80h offset = 20F\_0080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD1		X													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0		Y													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PXP\_OUT\_PS\_LRC field descriptions**

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the lower right X-coordinate (in pixels) of the processed surface (PS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.
13–0 Y	This field indicates the lower right Y-coordinate (in pixels) of the processed surface in the output frame buffer.

**38.7.10 Alpha Surface Upper Left Coordinate (PXP\_OUT\_AS\_ULC)**

This register contains the upper left location for the Alpha Surface in the output buffer.

This register contains the upper left coordinate of AS in the output frame buffer (in pixels). Values that are within the PXP\_OUT\_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the upper left coordinates will use the AS to render pixels in the output buffer.

**EXAMPLE**

```
PXP_OUT_AS_ULC_WR(0,0x0001_0001); // Alpha Surface upper left coordinate at (X,Y) = 1,1.
The AS surface will not effect pixels in the first row or first column of the output buffer.
```

Address: 20F\_0000h base + 90h offset = 20F\_0090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD1		X													
W

R	RSVD0		Y													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PXP\_OUT\_AS\_ULC field descriptions**

Field	Description
31–30 RSVD1	Reserved, always set to zero.

*Table continues on the next page...*

**PXP\_OUT\_AS\_ULC field descriptions (continued)**

Field	Description
29–16 X	This field indicates the upper left X-coordinate (in pixels) of the alpha surface (AS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.
13–0 Y	This field indicates the upper left Y-coordinate (in pixels) of the alpha surface in the output frame buffer.

### 38.7.11 Alpha Surface Lower Right Coordinate (PXP\_OUT\_AS\_LRC)

This register contains the lower right extent for Alpha Surface in the output buffer.

This register contains the lower right coordinate of AS in the output frame buffer (in pixels). Values that are within the PXP\_OUT\_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are less than or equal to the lower right coordinates will use the AS to render pixels in the output buffer.

#### EXAMPLE

```
PXP_AS_LRC_WR(0,0x03FF_03FF); // Alpha Surface lower right coordinate at (X,Y) = 1023,1023.
```

Address: 20F\_0000h base + A0h offset = 20F\_00A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD1		X													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	RSVD0		Y													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PXP\_OUT\_AS\_LRC field descriptions**

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the lower right X-coordinate (in pixels) of the alpha surface (AS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.

*Table continues on the next page...*

**PXP\_OUT\_AS\_LRC field descriptions (continued)**

Field	Description
13–0 Y	This field indicates the lower right Y-coordinate (in pixels) of the alpha surface in the output frame buffer.

### 38.7.12 Processed Surface (PS) Control Register (PXP\_PS\_CTRL)

The PS\_CTRL register contains controls for the Processed Surface Buffer.

PXP\_PS\_CTRL: 0x0B0

PXP\_PS\_CTRL\_SET: 0x0b4

PXP\_PS\_CTRL\_CLR: 0x0B8

PXP\_PS\_CTRL\_TOG: 0x0BC

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

#### EXAMPLE

```
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 20F\_0000h base + B0h offset = 20F\_00B0h

## PXP Memory Map/Register Definition

### PXP\_PS\_CTRL field descriptions

Field	Description
31–12 RSVD1	Reserved, always set to zero.
11–10 DECX	Horizontal pre decimation filter control.  0x0 <b>DISABLE</b> — Disable pre-decimation filter. 0x1 <b>DECX2</b> — Decimate PS by 2. 0x2 <b>DECX4</b> — Decimate PS by 4. 0x3 <b>DECX8</b> — Decimate PS by 8.
9–8 DECY	Verticle pre decimation filter control.  0x0 <b>DISABLE</b> — Disable pre-decimation filter. 0x1 <b>DECY2</b> — Decimate PS by 2. 0x2 <b>DECY4</b> — Decimate PS by 4. 0x3 <b>DECY8</b> — Decimate PS by 8.
7–6 RSVD0	Reserved, always set to zero.
5 WB_SWAP	Swap bytes in words. For each 16 bit word, the two bytes will be swapped.
4–0 FORMAT	PS buffer format. To select between YUV and YCbCr formats, see bit 31 of the CSC1_COEF0 register.  0x4 <b>RGB888</b> — 32-bit pixels (unpacked 24-bit format) 0xC <b>RGB555</b> — 16-bit pixels 0xD <b>RGB444</b> — 16-bit pixels 0xE <b>RGB565</b> — 16-bit pixels 0x10 <b>YUV1P444</b> — 32-bit pixels (1-plane XYUV unpacked) 0x12 <b>UYVY1P422</b> — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes) 0x13 <b>VYUY1P422</b> — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes) 0x14 <b>Y8</b> — 8-bit monochrome pixels (1-plane Y luma output) 0x15 <b>Y4</b> — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation) 0x18 <b>YUV2P422</b> — 16-bit pixels (2-plane UV interleaved bytes) 0x19 <b>YUV2P420</b> — 16-bit pixels (2-plane UV) 0x1A <b>YVU2P422</b> — 16-bit pixels (2-plane VU interleaved bytes) 0x1B <b>YVU2P420</b> — 16-bit pixels (2-plane VU) 0x1E <b>YUV422</b> — 16-bit pixels (3-plane format) 0x1F <b>YUV420</b> — 16-bit pixels (3-plane format)

### 38.7.13 PS Input Buffer Address (PXP\_PS\_BUF)

PS Input Buffer Address. This should be programmed to the starting address of the RGB data or Y (luma) data for the PS plane.

This register contains the pointer to the Luma/RGB buffer. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

#### EXAMPLE

```
PXP_PS_BUF_WR(image_rgb); // RGB image
PXP_PS_BUF_WR(image_y);  // Y (luma) image data
PXP_PS_UBUF_WR(image_u); // U (Cb) image data
PXP_PS_VBUF_WR(image_v); // V (Cr) image data
```

Address: 20F\_0000h base + C0h offset = 20F\_00C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### PXP\_PS\_BUF field descriptions

Field	Description
31–0 ADDR	Address pointer for the PS RGB or Y (luma) input buffer.

### 38.7.14 PS U/Cb or 2 Plane UV Input Buffer Address (PXP\_PS\_UBUF)

PS Chroma (U/Cb/UV) Input Buffer Address. This register points to the beginning of the PS U/Cb input buffer. In two plane operation, this register points to the beginning of the PS UV chroma input buffer.

This register contains the pointer to the Chroma U/Cb or 2 plane UV buffer. This register is unused when processing 1-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

#### EXAMPLE

```
PXP_PS_BUF_WR(image_y); // Y (luma) image data
PXP_PS_UBUF_WR(image_u); // U (Cb) image data
```

## PXP Memory Map/Register Definition

```
PXP_PS_VBUF_WR(image_v); // V (Cr) image data
```

Address: 20F\_0000h base + D0h offset = 20F\_00D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

### PXP\_PS\_UBUF field descriptions

Field	Description
31–0 ADDR	Address pointer for the PS U/Cb or 2 plane UV Chroma input buffer.

## 38.7.15 PS V/Cr Input Buffer Address (PXP\_PS\_VBUF)

PS Chroma (V/Cr) Input Buffer Address. This register points to the beginning of the PS V/Cr input buffer. In one or two plane operation, this register is not used. In monochrome modes Y8 and Y4, the low 16 bits are used as the U/V data in the datapath instead of sourcing U/V data from external buffers. In this case, it represents a fixed value for U/V data.

This register contains the pointer to the Chroma V/Cr buffer. For Y8/Y4 modes, the low 16 bits are used as the monochrome U and V values in the data path. Bits [15:8] represent the U data byte, and bits [7:0] represent the V data byte. Other than with Y8/Y4 input buffer formats, this register is unused when processing 1 or 2-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

### EXAMPLE

```
PXP_PS_BUF_WR(image_y); // Y (luma) image data
PXP_PS_UBUF_WR(image_u); // U (Cb) image data
PXP_PS_VBUF_WR(image_v); // V (Cr) image data
```

Address: 20F\_0000h base + E0h offset = 20F\_00E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**PXP\_PS\_VBUF field descriptions**

Field	Description
31–0 ADDR	Address pointer for the PS V/Cr Chroma input buffer.

**38.7.16 Processed Surface Pitch (PXP\_PS\_PITCH)**

This register contains the processed surface pitch in bytes.

Any byte value will indicate the vertical pitch of the PS source frame buffer. This value will be used in PS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input PS surface. For multi-plane formats, the Y buffer pitch should be programmed. For 2-plane YUV422, the UV pitch is the same as the Y pitch. For 3-plane YUV422, the U and V pitch is 1/2 the Y pitch. For 2-plane YUV420, the UV pitch is 1/2 the Y pitch. For 3-plane YUV420, the U and V pitch is 1/4 the Y pitch. All source buffers should comply with these U and V resolution reductions with respect to their Y source buffers.

**EXAMPLE**

```
PXP_PS_PITCH_WR( 64 * 4 ); // The output buffer pitch is 64 pixels times 32 bits per pixel
```

Address: 20F\_0000h base + F0h offset = 20F\_00F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD																PITCH															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**PXP\_PS\_PITCH field descriptions**

Field	Description
31–16 RSVD	Reserved, always set to zero.
15–0 PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

### 38.7.17 PS Background Color (PXP\_PS\_BACKGROUND)

PS Background Pixel Color. This register provides a pixel value used when processing pixels outside of the region specified by the PS Coordinate registers. This value can effectively be used to set the color of the letterboxing region around the PS image.

This register contains a pixel value to be used for any PS pixels that fall outside the PS extents. This is effectively a background or letterbox color. The CSC1 control and datapath pixel format should be considered when selecting the background color.

#### EXAMPLE

```
PXP_PS_BACKGROUND_WR(0x00000000); // letterbox is black
PXP_PS_BACKGROUND_WR(0x00800000); // letterbox is dark red
PXP_PS_BACKGROUND_WR(0x00008000); // letterbox is dark green
PXP_PS_BACKGROUND_WR(0x00000080); // letterbox is dark blue
```

Address: 20F\_0000h base + 100h offset = 20F\_0100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD								COLOR																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**PXP\_PS\_BACKGROUND field descriptions**

Field	Description
31–24 RSVD	Reserved, always set to zero.
23–0 COLOR	Background color (in 24bpp format) for any pixels not within the buffer range specified by the PS ULC/LRC.

### 38.7.18 PS Scale Factor Register (PXP\_PS\_SCALE)

PS Scale Factor. This register provides the scale factor for the PS buffer.

The maximum down scaling factor is 1/2 such that the output image in either axis is 1/2 the size of the source. The maximum up scaling factor is  $2^{12}$  for either axis. The reciprocal of the scale factor should be loaded into this register. To reduce the PS buffer by a factor of two in the output frame buffer, a value of 10.0000\_0000\_0000 should be loaded into this register. To scale up by a factor of 4, the value of 1/4, or 00.0100\_0000\_0000, should be loaded into this register. To scale up by 8/5, the value of 00.1010\_0000\_0000 should be loaded.

EXAMPLE

```
PXP_PS_SCALE_WR(0x10001000); // 1:1 scaling (0x1.000)
PXP_PS_SCALE_WR(0x08000800); // 2x scaling (0x0.800)
PXP_PS_SCALE_WR(0x20002000); // 1/2x scaling (0x2.000)
```

Address: 20F\_0000h base + 110h offset = 20F\_0110h

PXP\_PS\_SCALE field descriptions

Field	Description
31 RSVD2	Reserved, always set to zero.
30–16 YSCALE	This is a two bit integer and 12 bit fractional representation (##.####_####_####) of the Y scaling factor for the PS source buffer. The maximum value programmed should be 2 since scaling down by a factor greater than 2 is not supported with the bilinear filter. Decimation and the bilinear filter should be used together to achieve scaling by more than a factor of 2.
15 RSVD1	Reserved, always set to zero.
14–0 XSCALE	This is a two bit integer and 12 bit fractional representation (##.####_####_####) of the X scaling factor for the PS source buffer. The maximum value programmed should be 2 since scaling down by a factor greater than 2 is not supported with the bilinear filter. Decimation and the bilinear filter should be used together to achieve scaling by more than a factor of 2.

### 38.7.19 PS Scale Offset Register (PXP\_PS\_OFFSET)

PS Scale Offset. This register provides the initial scale offset for the PS buffer.

The X and Y offset provides the ability to access the source image with a per sub-pixel granularity. This provides the capability to use all source pixels to effect the output PS image. The fixed offset values can be used for sub-pixel adjustments in the bilinear scaling filter. For example, when scaling an image down by a factor of 2, an initial offset of 0x0 would result in sub-sampling every other pixel. If a fixed offset of 0x800 (1/2), all pixels are used in scaling the final output pixel value. In this case, the first output pixel would be the sum of  $(1/2 * P_0) + (1/2 * P_1)$ . This fixed offset is applied after the decimation filter stage, and before the bilinear filter stage.

#### EXAMPLE

```
PXP_PS_SCALE_WR(0x2000_2000); // 1/2x scaling (0x2.000)
PXP_PS_OFFSET_WR(0x0800_0800); // half-pixel offset in both X and Y to ensure averaging
versus pixel decimation
```

Address: 20F\_0000h base + 120h offset = 20F\_0120h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD2				YOFFSET												RSVD1				XOFFSET											
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### PXP\_PS\_OFFSET field descriptions

Field	Description
31–28 RSVD2	Reserved, always set to zero.
27–16 YOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the Y scaling offset. This represents a fixed pixel offset which gets added to the scaled address to determine source data for the scaling engine.
15–12 RSVD1	Reserved, always set to zero.
11–0 XOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the X scaling offset. This represents a fixed pixel offset which gets added to the scaled address to determine source data for the scaling engine.

### 38.7.20 PS Color Key Low (PXP\_PS\_CLRKEYLOW)

This register contains the color key low value for the PS buffer.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between PXP\_PS\_CLRKEYLOW and PXP\_PS\_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the PXP\_PS\_BACKGROUND color is passed down the pixel pipeline.

### EXAMPLE

```
// colorkey values between
PXP_PS_CLRKEYLOW_WR (0x008000); // medium green and
PXP_PS_CLRKEYHIGH_WR(0x00FF00); // light green
```

Address: 20F\_0000h base + 130h offset = 20F\_0130h

**PXP\_PS\_CLRKEYLOW field descriptions**

Field	Description
31–24 RSVD1	Reserved, always set to zero.
23–0 PIXEL	Low range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFFFF and the high colorkey to 0x000000.

### 38.7.21 PS Color Key High (PXP\_PS\_CLRKEYHIGH)

This register contains the color key high value for the PS buffer.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between PXP\_PS\_CLRKEYLOW and PXP\_PS\_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the PXP\_PS\_BACKGROUND color is passed down the pixel pipeline.

### EXAMPLE

```
// colorkey values between
PXP_PS_CLRKEYLOW_WR (0x008000); // medium green and
PXP_PS_CLRKEYHIGH_WR(0x00FF00); // light green
```

## PXP Memory Map/Register Definition

Address: 20F\_0000h base + 140h offset = 20F\_0140h

### PXP\_PS\_CLRKEYHIGH field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
23–0 PIXEL	High range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFFFF and the high colorkey to 0x000000.

## 38.7.22 Alpha Surface Control (PXP\_AS\_CTRL)

This register contains buffer control for the Alpha Surface 0 input buffer.

The Alpha Surface Parameter register provides additional controls for AS.

### EXAMPLE

```

u32 asparam;
    asparam = BF_PXP_ASPARAM_ENABLE      (1);
    asparam |= BF_PXP_ASPARAM_ALPHA_CTRL (BV_PXP_ASPARAM_ALPHA_CTRL_ROPS);
    asparam |= BF_PXP_ASPARAM_FORMAT     (BV_PXP_ASPARAM_FORMAT_ARGB8888);
    asparam |= BF_PXP_ASPARAM_ROP       (BV_PXP_ASPARAM_ROP_XORAS);
PXP_ASPARAM_WR(0,asparam); // enable alpha surface to perform XOR ROP using RGB8888 AS
pixel format

```

Address: 20F\_0000h base + 150h offset = 20F\_0150h

PXP\_AS\_CTRL field descriptions

Field	Description
31–21 RSVD1	Reserved, always set to zero.
20 ALPHA_INVERT	Setting this bit to logic 0 will not alter the alpha value. A logic 1 will invert the alpha value and apply (1-alpha) for image composition.
19–16 ROP	Indicates a raster operation to perform when enabled. Raster operations are enabled through the ALPHA_CTRL field.  0x0 <b>MASKAS</b> — AS AND PS 0x1 <b>MASKNOTAS</b> — nAS AND PS 0x2 <b>MASKASNOT</b> — AS AND nPS 0x3 <b>MERGEAS</b> — AS OR PS 0x4 <b>MERGENOTAS</b> — nAS OR PS 0x5 <b>MERGEASNOT</b> — AS OR nPS 0x6 <b>NOTCOPYAS</b> — nAS 0x7 <b>NOT</b> — nPS 0x8 <b>NOTMASKAS</b> — AS NAND PS 0x9 <b>NOTMERGEAS</b> — AS NOR PS 0xA <b>XORAS</b> — AS XOR PS 0xB <b>NOTXORAS</b> — AS XNOR PS
15–8 ALPHA	Alpha modifier used when the ALPHA_MULTIPLY or ALPHA_OVERRIDE values are programmed in PXP_AS_CTRL[ALPHA_CTRL]. The output alpha value will either be replaced (ALPHA_OVERRIDE) or scaled (ALPHA_MULTIPLY) when selected.
7–4 FORMAT	Indicates the input buffer format for AS.  0x0 <b>ARGB8888</b> — 32-bit pixels with alpha 0x4 <b>RGB888</b> — 32-bit pixels without alpha (unpacked 24-bit format) 0x8 <b>ARGB1555</b> — 16-bit pixels with alpha

Table continues on the next page...

**PXP\_AS\_CTRL field descriptions (continued)**

Field	Description
	0x9 <b>ARGB4444</b> — 16-bit pixels with alpha 0xC <b>RGB555</b> — 16-bit pixels without alpha 0xD <b>RGB444</b> — 16-bit pixels without alpha 0xE <b>RGB565</b> — 16-bit pixels without alpha
3 ENABLE_ COLORKEY	Indicates that colorkey functionality is enabled for this alpha surface. Pixels found in the alpha surface colorkey range will be displayed as transparent (the PS pixel will be used).
2–1 ALPHA_CTRL	Determines how the alpha value is constructed for this alpha surface. Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels.  0x0 <b>Embedded</b> — Indicates that the AS pixel alpha value will be used to blend the AS with PS. The ALPHA field is ignored. 0x1 <b>Override</b> — Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. 0x2 <b>Multiply</b> — Indicates that the value in the ALPHA field should be used to scale all pixel alpha values. Each pixel alpha is multiplied by the value in the ALPHA field. 0x3 <b>ROPs</b> — Enable ROPs. The ROP field indicates an operation to be performed on the alpha surface and PS pixels.
0 RSVD0	Reserved, always set to zero.

**38.7.23 Alpha Surface Buffer Pointer (PXP\_AS\_BUF)**

Alpha Surface 0 Buffer Address Pointer. This register points to the beginning of the Alpha Surface 0 input buffer.

This register is used to indicate the base address of the AS buffer.

**EXAMPLE**

```
u32* alpha_ptr;
PXP_ASn_WR(0, alpha_ptr);
```

Address: 20F\_0000h base + 160h offset = 20F\_0160h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**PXP\_AS\_BUF field descriptions**

Field	Description
31–0 ADDR	Address pointer for the alpha surface 0 buffer.

### 38.7.24 Alpha Surface Pitch (PXP\_AS\_PITCH)

This register contains the alpha surface pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in AS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input AS surface.

#### EXAMPLE

```
PXP_AS_PITCH_WR( 1920 * 4 ); // The output buffer pitch is HD resolution at 32 bits per pixel
```

Address: 20F\_0000h base + 170h offset = 20F\_0170h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD																PITCH															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### PXP\_AS\_PITCH field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
15–0 PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

### 38.7.25 Overlay Color Key Low (PXP\_AS\_CLRKEYLOW)

This register contains the color key low value for the AS buffer.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

#### EXAMPLE

```
// colorkey values between
PXP_AS_CLRKEYLOW_WR (0x000000); // black and
PXP_AS_CLRKEYHIGH_WR(0x800000); // medium red
```

## PXP Memory Map/Register Definition

Address: 20F\_0000h base + 180h offset = 20F\_0180h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### PXP\_AS\_CLRKEYLOW field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
23–0 PIXEL	Low range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

## 38.7.26 Overlay Color Key High (PXP\_AS\_CLRKEYHIGH)

This register contains the color key high value for the AS buffer.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

### EXAMPLE

```
// colorkey values between  
PXP_AS_CLRKEYLOW_WR (0x000000); // black and  
PXP_AS_CLRKEYHIGH_WR(0x800000); // medium red
```

Address: 20F\_0000h base + 190h offset = 20F\_0190h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

### PXP\_AS\_CLRKEYHIGH field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
23–0 PIXEL	High range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

### 38.7.27 Color Space Conversion Coefficient Register 0 (PXP\_CSC1\_COEF0)

This register contains color space conversion coefficients in two's complement notation.

The coefficient 0 register contains coefficients used in the color space conversion algorithm. The Y and UV offsets are added to the source buffer to normalize them before the conversion. C0 is the coefficient that is used to multiply the luma component of the data for all three RGB components.

#### EXAMPLE

```
// The equations used for Colorspace conversion are:
//   R = C0*(Y+YOFFSET) + C1(V+UV_OFFSET)
//   G = C0*(Y+YOFFSET) + C3(U+UV_OFFSET) + C2(V+UV_OFFSET)
//   B = C0*(Y+YOFFSET) + C4(U+UV_OFFSET)

PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 20F\_0000h base + 1A0h offset = 20F\_01A0h

**PXP\_CSC1\_COEF0 field descriptions**

Field	Description
31 YCBCR_MODE	Set to 1 when performing YCbCr conversion to RGB. Set to 0 when converting YUV to RGB data. This bit changes the behavior of the scaler when performing U/V scaling.
30 BYPASS	Bypass the CSC unit in the scaling engine. When set to logic 1, bypass is enabled and the output pixels will be in the YUV/YCbCr color space. When set to logic 0, the CSC unit is enabled and the pixels will be converted based on the programmed coefficients.
29 RSVD1	Reserved, always set to zero.
28–18 C0	Two's compliment Y multiplier coefficient. YUV=0x100 (1.000) YCbCr=0x12A (1.164)
17–9 UV_OFFSET	Two's compliment phase offset implicit for CbCr data. Generally used for YCbCr to RGB conversion. YCbCr=0x180, YUV=0x000 (typically -128 or 0x180 to indicate normalized -0.5 to 0.5 range)
8–0 Y_OFFSET	Two's compliment amplitude offset implicit in the Y data. For YUV, this is typically 0 and for YCbCr, this is typically -16 (0x1F0)

## 38.7.28 Color Space Conversion Coefficient Register 1 (PXP\_CSC1\_COEF1)

This register contains color space conversion coefficients in two's compliment notation.

The Coefficient 1 register contains coefficients used in the color space conversion algorithm. C1 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the red component. C4 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the blue component. Both values should be coded as a two's compliment fixed point number with 8 bits right of the decimal.

### EXAMPLE

```
PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UYoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 20F\_0000h base + 1B0h offset = 20F\_01B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**PXP\_CSC1\_COEF1 field descriptions**

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C1	Two's compliment Red V/Cr multiplier coefficient. YUV=0x123 (1.140) YCbCr=0x198 (1.596)
15–11 RSVD0	Reserved, always set to zero.
10–0 C4	Two's compliment Blue U/Cb multiplier coefficient. YUV=0x208 (2.032) YCbCr=0x204 (2.017)

### 38.7.29 Color Space Conversion Coefficient Register 2 (PXP\_CSC1\_COEF2)

This register contains color space conversion coefficients in two's compliment notation.

The Coefficient 2 register contains coefficients used in the color space conversion algorithm. C2 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the green component. C3 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the green component. Both values should be coded as a two's compliment fixed point number with 8 bits right of the decimal.

**EXAMPLE**

// NOTE: The default values for the CSCCOEF2 register are incorrect. C2 should be 0x76B and C3 should be 0x79C for proper operation.

```
PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UYoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 20F\_0000h base + 1C0h offset = 20F\_01C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## PXP\_CSC1\_COEF2 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C2	Two's complement Green V/Cr multiplier coefficient. YUV=0x76B (-0.581) YCbCr=0x730 (-0.813)
15–11 RSVD0	Reserved, always set to zero.
10–0 C3	Two's complement Green U/Cb multiplier coefficient. YUV=0x79C (-0.394) YCbCr=0x79C (-0.392)

### 38.7.30 Color Space Conversion Control Register. (PXP\_CSC2\_CTRL)

This register contains the control registers to configure the CSC module.

The CSC control register will configure the CSC module to perform color space conversion between the RGB/YUV/YCbCr color spaces.

#### EXAMPLE

```
//Converting from YUV/YCbCr color spaces to the RGB color space uses the
//following equation structure:
//
// R = A1(Y-D1) + A2(U-D2) + A3(V-D3)
// G = B1(Y-D1) + B2(U-D2) + B3(V-D3)
// B = C1(Y-D1) + C2(U-D2) + C3(V-D3)
//
//Converting from the RGB color space to YUV/YCbCr color spaces uses the
//following equation structure:
//
// Y = A1*R + A2*G + A3*B + D1
// U = B1*R + B2*G + B3*B + D2
// V = C1*R + C2*G + C3*B + D3
//
//All math is signed, so all coefficients come in as two's comp numbers
//
```

Address: 20F\_0000h base + 1D0h offset = 20F\_01D0h

PXP\_CSC2\_CTRL field descriptions

Field	Description
31–3 RSVD	Reserved, always set to zero.
2–1 CSC_MODE	This field controls how the CSC unit operates on pixels when the CSC is not bypassed. 0x0 <b>YUV2RGB</b> — Convert from YUV to RGB. 0x1 <b>YCbCr2RGB</b> — Convert from YCbCr to RGB. 0x2 <b>RGB2YUV</b> — Convert from RGB to YUV. 0x3 <b>RGB2YCbCr</b> — Convert from RGB to YCbCr.
0 BYPASS	This bit controls whether the pixels entering the CSC2 unit get converted or not. When BYPASS is set, no operations occur on the pixels. When BYPASS is cleared, the selected CSC operation takes place.

38.7.31 Color Space Conversion Coefficient Register 0 (PXP\_CSC2\_COEF0)

This register contains color space conversion coefficients in two's complement notation.

Address: 20F\_0000h base + 1E0h offset = 20F\_01E0h

**PXP\_CSC2\_COEF0 field descriptions**

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 A2	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
10–0 A1	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

### 38.7.32 Color Space Conversion Coefficient Register 1 (PXP\_CSC2\_COEF1)

This register contains color space conversion coefficients in two's complement notation.

Address: 20F\_0000h base + 1F0h offset = 20F\_01F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### PXP\_CSC2\_COEF5 field descriptions

Field	Description
31–25 RSVD1	Reserved, always set to zero.
24–16 D3	Two's complement coefficient integer offset to be added.
15–9 RSVD0	Reserved, always set to zero.
8–0 D2	Two's complement D1 coefficient integer offset to be added.

## 38.7.37 Lookup Table Control Register. (PXP\_LUT\_CTRL)

This register is used to access/control the Monochrome Lookup table.

The Y8 LUT input mode will take the high order data path byte and transform it using the LUT memory. This is an 8-bit to 8-bit transformation. The two low order bytes bypass the LUT and are not transformed, but bypassed without modification. This option can be used for monochrome gamma correction. The Direct Lookup mode will use the high nibble of each data byte and truncate the low nibble to generate the lookup address, i.e. R[7:0]G[7:0]B[7:0] -> R[7:4]G[7:4]B[7:4]. 4K pixels (12-bit address) with 2 bytes per pixel is supported in this mode. Cached Lookup mode will use the high order bits, R[7:3],G[7:2],B[7:3] or RGB565, to address the cached LUT memory. 64KB LUT tables, using 16KB of internal LUT memory, can be indirectly transformed to 16-bit output pixels (as in RGBW4444/RGB565). This is used for 16bpp gamma correction or EPD color panel support. Cache misses are internally managed by the PXP LUT Cache controller.

## PXP Memory Map/Register Definition

Address: 20F\_0000h base + 240h offset = 20F\_0240h

### PXP\_LUT\_CTRL field descriptions

Field	Description
31 BYPASS	Setting this bit will bypass the LUT memory resource completely. No pixel transformations will occur at this stage of the PXP pixel rprocessing pipeline.
30–26 RSVD3	Reserved, always set to zero.
25–24 LOOKUP_MODE	Configure the input address for the 16KB LUT memory. The address into the LUT uses different parts of the pixel data path bytes. The data path is defined as three bytes, conceptually as RGB/YUV/YCbCr[23:0]. Also referred to as R/Y[7:0],G/U[7:0],B/V[7:0]  0x0 <b>CACHE_RGB565</b> — LUT ADDR = R[7:3],G[7:2],B[7:3]. Use all 16KB of LUT for indirect cached 128KB lookup. 0x1 <b>DIRECT_Y8</b> — LUT ADDR = 16'b0,Y[7:0]. Use only the first 256 bytes of LUT. Only the Y, or third data path byte, is tranformed. 0x2 <b>DIRECT_RGB444</b> — LUT ADDR = R[7:4],G[7:4],B[7:4]. Use one 8KB bank of LUT selected by SEL_8KB. 0x3 <b>DIRECT_RGB454</b> — LUT ADDR = R[7:4],G[7:3],B[7:4]. Use all 16KB of LUT.
23–18 RSVD2	Reserved, always set to zero.

Table continues on the next page...

**PXP\_LUT\_CTRL field descriptions (continued)**

Field	Description
17–16 OUT_MODE	Select the output mode of operation for the LUT resource. There are four bytes [3-0] in the data path at the output of the LUT resource. Byte lane 3 is always bypassed and usually contains an alpha value. The LUT can be programmed to transform bytes 2,1,0 according to the options available in this field.  0x0 <b>RESERVED</b> — Reserved, not valid when using the LUT to transform pixels. 0x1 <b>Y8</b> — R/Y byte lane 2 lookup, bytes 1,0 bypassed. 0x2 <b>RGBW4444CFA</b> — Byte lane 2 = CFA_Y8, byte lane 1,0 = RGBW4444. 0x3 <b>RGB888</b> — RGB565->RGB888 conversion for Gamma correction.
15–11 RSVD1	Reserved, always set to zero.
10 SEL_8KB	Selects which 8KB bank of memory to use for direct 12bpp lookup modes. Logic 0 indicates first 8KB, logic 1 indicates second 8KB. Two direct LUT arrays can be stored and one can be selected for a given PXP operation.
9 LRU_UPD	Least Recently Used Policy Update Control: 1=> block LRU update for hit after miss. 0=> update LRU for all hits including hit after miss.
8 INVALID	Invalidate the cache LRU and valid bits. This bit will automatically reset when set to a logic 1.
7–1 RSVD0	Reserved, always set to zero.
0 DMA_START	Setting this bit will result in the DMA operation to load the PXP LUT memory based on PXP_LUT_ADDR_NUM_BYTES, PXP_LUT_ADDR_ADDR, and PXP_LUT_MEM_ADDR.  This bit will automatically reset when set to a logic 1. Note: The LOOKUP_MODE must not be set to CACHE_RGB565 when starting and performing DMA transfers.

**38.7.38 Lookup Table Control Register. (PXP\_LUT\_ADDR)**

This register is used to access/control the Monochrome Lookup table.

The Y8 LUT input mode will take the high order data path byte and transform it using the LUT memory. This is an 8-bit to 8-bit transformation. The two low order bytes bypass the LUT and are not transformed, but bypassed without modification. This option can be used for monochrome gamma correction. The Direct Lookup mode will use the high nibble of each data byte and truncate the low nibble to generate the lookup address, i.e. R[7:0]G[7:0]B[7:0] -> R[7:4]G[7:4]B[7:4]. 4K pixels (12-bit address) with 2 bytes per pixel is supported in this mode. Cached Lookup mode will use the high order bits, R[7:3],G[7:2],B[7:3] or RGB565, to address the cached LUT memory. 64KB LUT tables, using 16KB of internal LUT memory, can be indirectly transformed to 16-bit output

## PXP Memory Map/Register Definition

pixels (as in RGBW4444/RGB565). This is used for 16bpp gamma correction or EPD color panel support. Cache misses are internally managed by the PXP LUT Cache controller.

Address: 20F\_0000h base + 250h offset = 20F\_0250h

### PXP\_LUT\_ADDR field descriptions

Field	Description
31 RSVD2	Reserved, always set to zero.
30–16 NUM_BYTES	Indicates the number of bytes to load via a DMA operation. This field must be divisible by 8 and the least significant 3 bits must be 0. The value 8 indicates load 8 bytes from the external address indicated by PXP_LUT_MEM_ADDR to the LUT memory location indicated by PXP_LUT_CTRL_ADDR.
15–14 RSVD1	Reserved, always set to zero.
13–0 ADDR	LUT indexed address pointer. This address into the LUT memory is always four byte aligned for PIO access, and eight byte aligned for DMA access.  The least two significant bits are not used to drive the LUT memory array. For PIO LUT access, when the LUT data register is written, the contents of the LUT at the address specified by this address field will be loaded with a 32-bit DWORD. This address pointer will be incremented after the LUT data is written. This will provide recursive writes to the LUT data register to initialize the entire LUT array with recursive writes to the LUT data register. For DMA access, this register indicates the LUT memory address of the 8 byte QWORD to be loaded. When using the NUM_BYTES field to load more than 8 bytes, the register should be programmed with the first LUT memory location to be filled and each load of the LUT memory will increment this address field until NUM_BYTES has been loaded.

### 38.7.39 Lookup Table Data Register. (PXP\_LUT\_DATA)

This register is used to load data into the lookup table.

Address: 20F\_0000h base + 260h offset = 20F\_0260h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### PXP\_LUT\_DATA field descriptions

Field	Description
31–0 DATA	Writing this field will load 4 bytes, aligned to four byte boundaries, of data indexed by the ADDR field of the PXP_LUT_CTRL register.

### 38.7.40 Lookup Table External Memory Address Register. (PXP\_LUT\_EXTMEM)

For DMA LUT memory loads, this is the base address from which data will be sourced to store into the LUT memory array. For Cached LUT memory pixel transformations, this register will store the base address of the full 64K pixel LUT translation table.

Address: 20F\_0000h base + 270h offset = 20F\_0270h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ADDR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

#### PXP\_LUT\_EXTMEM field descriptions

Field	Description
31–0 ADDR	This register contains the external memory address used for LUT memory operation. For DMA LUT memory loads, this is the base address from which data will be sourced to store into the LUT memory array. For Cached LUT memory pixel transformations, this register will store the base address of the full 64K pixel LUT translation table.

38.7.41 Color Filter Array Register. (PXP\_CFA)

There are sixteen 2 bit values in this register each mapping a selected component to the output pixel. The two bit values are defined as 0=>R, 1=>G, 2=>B, and 3=>W. The first byte represents the repetitive pattern of RGBW pixels in the CFA for the first line segment of each processed PXP block. The second byte represents the pattern in the second line segment of the block, and so on. The first byte repeats two times for 8x8 macro block mode, and repeats four times for 16x16 block mode.

Address: 20F\_0000h base + 280h offset = 20F\_0280h

PXP\_CFA field descriptions

Field	Description
31–0 DATA	This register contains the Color Filter Array pattern for decimation of RGBW4444 16 bit pixels to individual R, G, B, W values. The pattern represents a replicated 4x4 color filter array for the entire output frame buffer.

38.7.42 Histogram Control Register. (PXP\_HIST\_CTRL)

Provides control and status registers for the PXP's histogram classification algorithm.

Address: 20F\_0000h base + 290h offset = 20F\_0290h

PXP\_HIST\_CTRL field descriptions

Field	Description
31–6 RSVD	Reserved, always set to zero.
5–4 PANEL_MODE	<p>Specifies the EPDC panel grayscale depth. This value is used to specify the number of bits used in comparisons when matching pixels to histogram bins.</p> <p>All comparator values <b>MUST</b> be programmed such that their bit width is consistent with the value of this register field.</p> <p>For instance, if GRAY16 is selected, comparator values must be in the range of 0x0-0xF.</p> <p>0x0   <b>GRAY4</b> — 4-bit grayscale 0x1   <b>GRAY8</b> — 8-bit grayscale 0x2   <b>GRAY16</b> — 16-bit grayscale 0x3   <b>GRAY32</b> — 32-bit grayscale</p>
3–0 STATUS	<p>Indicates which histogram matched the processed bitmap.</p> <p>Bit[0] indicates that the bitmap pixels were fully contained within the HIST2 (black / white) histogram.</p> <p>Bit[1] indicates that the bitmap pixels were fully contained within the HIST4 (2-bit grayscale) histogram.</p> <p>Bit[2] indicates that the bitmap pixels were fully contained within the HIST8 (3-bit grayscale) histogram.</p> <p>Bit[3] indicates that the bitmap pixels were fully contained within the HIST16 (4-bit grayscale) histogram.</p>

38.7.43 2-level Histogram Parameter Register.  
(PXP\_HIST2\_PARAM)

This register specifies the valid values for a 2-level histogram. If all pixels in a bitmap match the 2-level histogram values, STATUS[0] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL\_MODE control field.

## PXP Memory Map/Register Definition

Address: 20F\_0000h base + 2A0h offset = 20F\_02A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**PXP\_HIST16\_PARAM3 field descriptions**

Field	Description
31–29 RSVD15	Reserved, always set to zero.
28–24 VALUE15	GRAY15 (White) value for 16-level histogram
23–21 RSVD14	Reserved, always set to zero.
20–16 VALUE14	GRAY14 value for 16-level histogram
15–13 RSVD13	Reserved, always set to zero.
12–8 VALUE13	GRAY13 value for 16-level histogram
7–5 RSVD12	Reserved, always set to zero.
4–0 VALUE12	GRAY12 value for 16-level histogram

### 38.7.51 PXP Power Control Register. (PXP\_POWER)

Address: 20F\_0000h base + 320h offset = 20F\_0320h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CTRL																ROT_MEM_LP_STATE		LUT_LP_STATE_WAY1_BANKN		LUT_LP_STATE_WAY0_BANKN		LUT_LP_STATE_WAY0_BANK0									
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### PXP\_POWER field descriptions

Field	Description
31–12 CTRL	This register contains power control for the PXP.
11–9 ROT_MEM_LP_STATE	Select the low power state of the ROT memory. 0x0 <b>NONE</b> — Memory is not in low power state. 0x1 <b>LS</b> — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 <b>DS</b> — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 <b>SD</b> — Shut Down Mode. Shut Down periphery and core, no memory retention.
8–6 LUT_LP_STATE_WAY1_BANKN	Select the low power state of the LUT's WAY0-BANK0,1,2,3 memory. 0x0 <b>NONE</b> — Memory is not in low power state. 0x1 <b>LS</b> — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 <b>DS</b> — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 <b>SD</b> — Shut Down Mode. Shut Down periphery and core, no memory retention.
5–3 LUT_LP_STATE_WAY0_BANKN	Select the low power state of the LUT's WAY0-BANK1,2,3 memory. 0x0 <b>NONE</b> — Memory is not in low power state. 0x1 <b>LS</b> — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 <b>DS</b> — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 <b>SD</b> — Shut Down Mode. Shut Down periphery and core, no memory retention.
2–0 LUT_LP_STATE_WAY0_BANK0	Select the low power state of the LUT's WAY0-BANK0 memory. 0x0 <b>NONE</b> — Memory is not in low power state. 0x1 <b>LS</b> — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 <b>DS</b> — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 <b>SD</b> — Shut Down Mode. Shut Down periphery and core, no memory retention.

### 38.7.52 Next Frame Pointer (PXP\_NEXT)

This register contains a pointer to a data structure used to reload the PXP registers at the end of the current frame.

To enable this functionality, software must write this register while the PXP is processing the current data frame (if the PXP is currently idle, this will also initiate an immediate load of registers from the pointer). The process of writing this register (WRITE operation) will set a semaphore in hardware to notify the control logic that a register reload operation must be performed when the current frame processing is complete. At the end of a frame, the PXP will fetch the register settings from this location, signal an interrupt to software, then proceed with rendering the next frame of data. Software may cancel the reload operation by issuing a CLEAR operation to this register. SET and TOGGLE operations should not be used when addressing this register. All registers will be reloaded with the exception of the following: STAT, CSCCOEFn, NEXT. All other registers will be loaded in the order they appear in the register map. Once the pointer's contents have been loaded into the PXP's registers, the NEXT\_IRQ interrupt will be issued (see the PXP\_STATUS register).

#### EXAMPLE

```
// create register command structure in memory
u32* pxp_commands0[48], pxp_commands1;
u32 rc;

// initialize control structure for frame 0
pxp_commands0[0] = ...; // CTRL
pxp_commands0[1] = ...; // OUT Buffer
...
pxp_commands0[47] = ...; // Overlay7 param2

// initialize control structure for frame 1
pxp_commands1[0] = ...; // CTRL
pxp_commands1[1] = ...; // OUT Buffer
...
pxp_commands1[47] = ...; // Overlay7 param2

// poll until a command isn't queued
while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED );
PXP_NEXT_WR(pxp_commands0); // enable PXP operation 0 via command pointer

// poll until first command clears
while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED );
PXP_NEXT_WR(pxp_commands1); // enable PXP operation 1 via command pointer
```

Address: 20F\_0000h base + 400h offset = 20F\_0400h

PXP\_NEXT field descriptions

Field	Description
31–2 POINTER	A pointer to a data structure containing register values to be used when processing the next frame. The pointer must be 32-bit aligned and should reside in on-chip or off-chip memory.
1 RSVD	Reserved, always set to zero.
0 ENABLED	Indicates that the "next frame" functionality has been enabled. This bit reflects the status of the hardware semaphore indicating that a reload operation is pending at the end of the current frame.

# Chapter 39

## Random Number Generator (RNGB)

### 39.1 Introduction

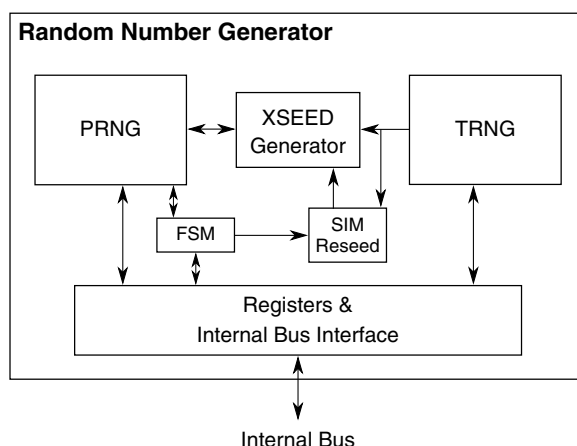

The purpose of the RNGB is to generate cryptographically strong random data.

It uses a true random number generator (TRNG) and a pseudo-random number generator (PRNG) to achieve true randomness and cryptographic strength. The RNGB generates random numbers for secret keys, per message secrets, random challenges, and other similar quantities used in cryptographic algorithms.

This chapter describes the random number generator (RNGB), including a programming model, functional description, and application information.

#### 39.1.1 Block Diagram

The below figure shows the RNGB's three main blocks: PRNG, TRNG, and XSEED generator.

**Figure 39-1. RNG Block Diagram**

### 39.1.2 Features

The RNG includes these distinctive features:

- National Institute of Standards and Technology (NIST)-approved pseudo-random number generator
  - <http://csrc.nist.gov>
- Supports the key generation algorithm defined in the Digital Signature Standard
  - <http://www.itl.nist.gov/fipspubs/fip186.htm>
- Integrated entropy sources capable of providing the PRNG with entropy for its seed.

## 39.2 Modes of Operation

Operational modes of the RNGB can be found here.

### 39.2.1 Self Test Mode

In this mode the RNGB performs a self test of the statistical counters and the PRNG algorithm to verify that the hardware is functioning properly. The self test takes ~29,000 cycles to complete. When self test completes an interrupt may be generated, if there are no outstanding commands in the command register. This mode is entered by setting the RNG\_CMD[ST] bit. When self test mode completes, the RNGB remains idle until seed mode is requested or the RNGB transitions to seed mode if automatic seeding is enabled.

### 39.2.2 Seed Generation Mode

During seed generation, the RNGB adds entropy generated in the TRNG to the 256-bit XKEY register. The PRNG algorithm executes 20,000 times sampling the entropy from the TRNG to create an initial seed for random number generation. At the same time, the TRNG runs simple statistical tests on its output.

When seed generation is complete, the TRNG reports the pass/fail result of the tests through RNG\_ESR. If the new seed passes the statistical tests, RNG\_SR[SDN] is set, signalling that the RNG is ready to compute secure pseudo-random data. The RNG then transitions to random number generation mode.

### 39.2.3 Random Number Generation Mode

When seed generation mode completes and the output FIFO is empty, the RNG enters this mode automatically. Random number generation mode quickly creates computationally random data that is derived by the initial seed produced in seed generation mode.

During random number generation, a new 160-bit random number is generated whenever the five word output FIFO is empty. When the output FIFO contains data, the RNGB automatically enters sleep mode, waiting for the data to be read. When the data is read, the RNGB generates a new 160-bit word and goes back to sleep.

After generating  $2^{20}$  words of random data, the RNGB lets the user know that it requires reseeding through RNG\_SR and continues to generate random data until it is directed to reseed. However, if auto-seeding is selected, the RNGB automatically completes seeding whenever it is needed.

### 39.2.4 Verification Mode

This mode is not a stand-alone mode in that it actually incorporates the previously mentioned three modes: seed generation, entropy generation, and random number generation. When the RNGB is in this mode the three modes behave in a deterministic way. This is done by replacing the TRNG's output with a deterministic sequence. This mode is entered by writing the verification mode bit in the control register.

## 39.3 Memory Map/Register Definition

The following table shows the address map for the RNGB module. Detailed register descriptions are found in the following sections.

**RNG memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
21B_4000	RNGB Version ID Register (RNG_VER)	32	R	1000_0280h	<a href="#">39.3.1/2372</a>
21B_4004	RNGB Command Register (RNG_CMD)	32	R/W	0000_0000h	<a href="#">39.3.2/2373</a>
21B_4008	RNGB Control Register (RNG_CR)	32	R/W	0000_0000h	<a href="#">39.3.3/2374</a>
21B_400C	RNGB Status Register (RNG_SR)	32	R	0000_500Dh	<a href="#">39.3.4/2376</a>
21B_4010	RNGB Error Status Register (RNG_ESR)	32	R	0000_0000h	<a href="#">39.3.5/2378</a>

*Table continues on the next page...*

## RNG memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
21B_4014	RNGB Output FIFO (RNG_OUT)	32	R	0000_0000h	<a href="#">39.3.6/2380</a>
21B_4018	RNGB Entropy Register (RNG_ER)	32	W (always reads 0)	0000_0000h	<a href="#">39.3.7/2380</a>

21B_4030	Oscillator Counter Status (RNG_OSC_CNT_STAT)	32	R	0000_0000h	<a href="#">39.3.12/2384</a>

## 39.3.1 RNGB Version ID Register (RNG\_VER)

The read-only RNG\_VER register contains the current version of the RNGB. It consists of the RNG type and major and minor revision numbers.

Address: 21B\_4000h base + 0h offset = 21B\_4000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TYPE				0												MAJOR				MINOR											
W																																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0

## RNG\_VER field descriptions

Field	Description
31–28 TYPE	Random number generator type  0000 RNGA 0001 RNGB (This is the type used in this module) 0010 RNGC Else Reserved
27–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–8 MAJOR	Major version number.  This field is always set to 0x02.
7–0 MINOR	Minor version number.  Subject to change.

### 39.3.2 RNGB Command Register (RNG\_CMD)

RNG\_CMD controls the RNG's operating modes and interrupt status.

Address: 21B\_4000h base + 4h offset = 21B\_4004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0									0	0	0	0			
W										SR	CE	CI			GS	ST
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**RNG\_CMD field descriptions**

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 SR	Software reset.  Performs a software reset of the RNGB. This bit is self-clearing.  0 Do not perform a software reset. 1 Software reset.
5 CE	Clear error.  Clears the errors in the RNG_ESR register and the RNGB interrupt. This bit is self-clearing.  0 Do not clear errors and interrupt. 1 Clear errors and interrupt.
4 CI	Clear interrupt.  Clears the RNGB interrupt if an error is not present. This bit is self-clearing.  0 Do not clear interrupt. 1 Clear interrupt.
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 GS	Generate seed.  Initiates the seed generation process. Seed generation starts <ul style="list-style-type: none"> <li>When RNG_SR[BUSY] is cleared</li> <li>If set simultaneously with ST, after self-test</li> </ul> When the seed generation process completes, this bit automatically clears and an interrupt may be generated if all requested operations are complete.

*Table continues on the next page...*

**RNG\_CMD field descriptions (continued)**

Field	Description
	0 Not in seed generation mode. 1 Generate seed mode.
0 ST	Self test.  Initiates a self test of the RNGB's internal logic. The self-test starts <ul style="list-style-type: none"> <li>• When RNG_SR[BUSY] is cleared, or</li> <li>• If set simultaneously with GS, self test takes precedence and is completed first.</li> </ul> When self test completes, this bit automatically clears and an interrupt may be generated if all requested operations are complete.  0 Not in self test mode. 1 Self test mode.

**39.3.3 RNGB Control Register (RNG\_CR)**

Through use of this register, the RNGB can be programmed to provide slightly different functionality based on its desired use.

Address: 21B\_4000h base + 8h offset = 21B\_4008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				0				MASKERR		MASKDONE		AR		0	
W

**RNG\_CR field descriptions**

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

## RNG\_CR field descriptions (continued)

Field	Description
6 MASKERR	<p>Mask error interrupt.</p> <p>Masks interrupts generated by errors in the RNGB. These errors can still be viewed in RNG_ESR.</p> <p><b>NOTE:</b> Since masked errors do not interrupt the operation of the RNGB and thus hide potentially fatal errors or conditions that could result in corrupted results, it is strongly recommended that errors only be masked while debugging. All errors are considered fatal, requiring the RNGB to be reset. Until the a reset occurs, the RNGB does not service any random data.</p> <p>0 No mask applied. 1 Mask applied to the error interrupt.</p>
5 MASKDONE	<p>Mask done interrupt.</p> <p>Masks interrupts generated upon completion of seed and self test modes. The status of these jobs can be viewed by:</p> <ul style="list-style-type: none"> <li>• Reading RNG_SR and viewing the seed done and self test done bits (RNG_SR[SDN, STDN])</li> <li>• Viewing RNG_CMD for generate seed or self test bits (RNG_CMD[GS,ST]) being set, indicating that the operation is still taking place.</li> </ul> <p>0 No mask applied. 1 Mask applied.</p>
4 AR	<p>Auto-reseed.</p> <p>Setting this bit allows the RNGB to automatically generate a new seed whenever one is needed. This allows software to never use the RNG_CMD[GS], although it is still possible. A new seed is needed whenever the RNG_SR[RS] is set.</p> <p>0 Do not enable automatic reseeding. 1 Enable automatic reseeding.</p>
3–2 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
1–0 FUFMOD	<p>FIFO underflow response mode.</p> <p>Controls the RNGB's response to a FIFO underflow condition.</p> <p>00 Return all zeros and set RNG_ESR[FUFE] 01 Return all zeros and set RNG_ESR[FUFE] 10 Generate bus transfer error 11 Generate interrupt and return all zeros (Overrides RNG_CR[MASKERR])</p>

### 39.3.4 RNGB Status Register (RNG\_SR)

The RNGBSR is a read-only register which reflects the internal status of the RNGB.

Address: 21B\_4000h base + Ch offset = 21B\_400Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	STATPF								ST_PF			0				ERR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	FIFO_SIZE				FIFO_LVL				0	NSDN	SDN	STDN	RS	SLP	BUSY	1
W																
Reset	0	1	0	1	0	0	0	0	0	0	0	0	1	1	0	1

**RNG\_SR field descriptions**

Field	Description
31–24 STATPF	<p>Statistics test pass fail.</p> <p>Indicates pass or fail status of the various statistics tests on the last seed generated.</p> <ul style="list-style-type: none"> <li>• Bit 31 - Long run test (&gt;34)</li> <li>• Bit 30 - Length 6+ run test</li> <li>• Bit 29 - Length 5 run test</li> <li>• Bit 28 - Length 4 run test</li> <li>• Bit 27 - Length 3 run test</li> <li>• Bit 26 - Length 2 run test</li> <li>• Bit 25 - Length 1 run test</li> <li>• Bit 24 - Monobit test</li> </ul> <p>0 Pass. 1 Fail.</p>
23–21 ST_PF	<p>Self Test Pass Fail.</p> <p>Indicates Pass or Fail status of the TRNG, PRNG, and RESEED self tests,</p> <ul style="list-style-type: none"> <li>• Bit 23 - TRNG self test pass/fail</li> </ul>

*Table continues on the next page...*

**RNG\_SR field descriptions (continued)**

Field	Description
	<ul style="list-style-type: none"> <li>• Bit 22 - PRNG self test pass/fail</li> <li>• Bit 21 - RESEED self test pass/fail</li> </ul> <p>0 Pass.</p> <p>1 Fail.</p>
20–17 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
16 ERR	<p>Error.</p> <p>Indicates an error was detected in the RNGB. Read the RNG_ESR register for details.</p> <p>0 No error.</p> <p>1 Error detected.</p>
15–12 FIFO_SIZE	<p>FIFO size.</p> <p>Size of the FIFO, and maximum possible FIFO level. The bits should be interpreted as an integer. This value is set to five on the default version of RNGB.</p>
11–8 FIFO_LVL	<p>FIFO level.</p> <p>Indicates the number of random words currently in the output FIFO. The bits should be interpreted as an integer.</p>
7 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
6 NSDN	<p>New seed done.</p> <p>Indicates that a new seed is ready for use during the next seed generation process.</p>
5 SDN	<p>Seed done.</p> <p>Indicates the RNG has generated the first seed.</p> <p>0 Seed generation process not complete.</p> <p>1 Completed seed generation since the last reset.</p>
4 STDN	<p>Self test done.</p> <p>Indicates the self test is complete. This bit is cleared by hardware reset or a new self test is initiated by setting RNG_CMD[ST].</p> <p>0 Self test not complete.</p> <p>1 Completed a self test since the last reset.</p>
3 RS	<p>Reseed needed.</p> <p>Indicates the RNGB needs to be reseeded. This is done by setting RNG_CMD[GS], or automatically if RNG_CR[AR] is set.</p> <p>0 RNGB does not need to be reseeded.</p> <p>1 RNGB needs to be reseeded.</p>
2 SLP	<p>Sleep.</p> <p>Indicates if the RNGB is in sleep mode. When set, the RNGB is in sleep mode and all internal clocks are disabled. While in this mode, access to the FIFO is allowed. Once the FIFO is empty, the RNGB fills the FIFO and then enters sleep mode again.</p>

*Table continues on the next page...*

**RNG\_SR field descriptions (continued)**

Field	Description
	0 RNGB is not in sleep mode. 1 RNGB is in sleep mode.
1 BUSY	Busy.  Reflects the current state of RNGB. If RNGB is currently seeding, generating the next seed, creating a new random number, or performing a self test, this bit is set.  0 Not busy. 1 Busy.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.

**39.3.5 RNGB Error Status Register (RNG\_ESR)**

Address: 21B\_4000h base + 10h offset = 21B\_4010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**RNG\_ESR field descriptions**

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

**RNG\_ESR field descriptions (continued)**

<b>Field</b>	<b>Description</b>
4 FUFE	<p>FIFO underflow error</p> <p>Indicates the RNGB has experienced a FIFO underflow condition resulting in the last random data read being unreliable. This bit can be masked by RNG_CR[FUFMOD] and is cleared by hardware or software reset or by writing one to RNG_CMD[CE].</p> <p>0 FIFO underflow has not occurred. 1 FIFO underflow has occurred</p>
3 SATE	<p>Statistical test error.</p> <p>Indicates if RNGB has failed the statistical tests for the last generated seed. This bit is sticky and is cleared by a hardware or software reset or by writing one to RNG_CMD[CE].</p> <p>0 RNGB has not failed the statistical tests. 1 RNGB has failed the statistical tests during initialization.</p>
2 STE	<p>Self test error.</p> <p>Indicates the RNGB has failed the most recent self test. This bit is sticky and can only be reset by a hardware reset or by writing one to RNG_CMD[CE].</p> <p>0 RNGB has not failed self test. 1 RNGB has failed self test.</p>
1 OSCE	<p>Oscillator error.</p> <p>Indicates the oscillator in the RNG may be broken. This bit is sticky and can only be cleared by a software or hardware reset.</p> <p>0 RNG oscillator is working properly. 1 Problem detected with the RNG oscillator.</p>
0 LFE	<p>Linear feedback shift register (LFSR) error.</p> <p>When this bit is set, the interrupt generated was caused by a failure of one of the LFSRs in one of the RNGB's three entropy sources. This bit is sticky and can only be cleared by a software or hardware reset.</p> <p>0 LFSRs are working properly. 1 LFSR failure has occurred.</p>

### 39.3.6 RNGB Output FIFO (RNG\_OUT)

The RNGBOU provides temporary storage for random data generated by the RNGB. This allows the user to read multiple random longwords back-to-back. A read of this address when the FIFO is not empty, returns 32 bits of random data. If the FIFO is read when empty, a FIFO underrun response is returned according to RNG\_CR[FUFMOD]. For optimal system performance, poll RNG\_SR[FIFO\_LVL] to ensure random values are present before reading the FIFO.

Address: 21B\_4000h base + 14h offset = 21B\_4014h

RNG\_OUT field descriptions

Field	Description
31–0 RANDOUT	Random Output

### 39.3.7 RNGB Entropy Register (RNG\_ER)

This read-only register can only be accessed when the RNGB is in Control Access Mode. The RNGBER is a write-only register which allows the user to insert entropy into the RNGB. When written this register causes an addition of the write data to the XKEY within the RNGB. If the system has a means to collect quality entropy (user key strokes or other random patterns), this is the way to add it directly into the accumulated entropy within the RNGB. Writing the RNG\_ER does not have a detrimental effect on the quality of random numbers as the number written is added to the state, not used to replace the existing state. Writing all zeros to the entropy register does nothing to the quality of random numbers generated.

**NOTE**

This register can only be written when the RNG is not busy (RNG\_SR[BUSY] = 0).

Address: 21B\_4000h base + 18h offset = 21B\_4018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																															
W	ENT																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

### RNG\_ER field descriptions

Field	Description
31–0 ENT	Entropy input.  This value is added directly to the internal state of the RNGB thus modifying its internal state and affecting future random numbers generated by the RNGB.

## 39.3.8 Verification Control Register (RNG\_VCR)

This register cannot be accessed when RNGB is in Control Access Mode. Through use of this register, the RNGB can be placed in a deterministic mode allowing verification of the design.

Address: 21B\_4000h base + 20h offset = 21B\_4020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0						0	0	0							
W							RST_XKEY	RST_SHREG					FAKE_SEED	OSC_TEST	FRC_SYS_CLK	SH_CLK_OFF
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**RNG\_VCR field descriptions**

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 RST_XKEY	Reset XKEY Register. Reset the internal state of the RNGB.
8 RST_SHREG	Reset Shift Registers. Reset the internal LFSRs to a known state.
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 FAKE_SEED	Fake Seed. This allows for quicker structural simulation by faking the seed process, which takes 2000000 cycles.
2 OSC_TEST	Oscillator Frequency Test. This can be set to enable the oscillator for oscillator frequency testing.
1 FRC_SYS_CLK	Force System Clock. This can be set to force the oscillator shift registers to use the system clock for additional test coverage.
0 SH_CLK_OFF	Shift Clocks Off. This can be set to shut off the shift register clocks.

**39.3.9 XKEY Data (RNG\_XKEY)**

This read-only register can only be accessed when the RNGB is in Control Access Mode. The register is used to read out the internal state of the PRNG one 32-bit word at a time. Since the structure is 256-bits, it takes eight reads to read out the entire contents. If reads of this register are not done in multiples of eight, the next group of random data generated will not correctly reflect the state of the RNGB. This register will only return relevant data when the RNGB is not busy.

Address: 21B\_4000h base + 24h offset = 21B\_4024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	XKEY																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**RNG\_XKEY field descriptions**

Field	Description
31–0 XKEY	32-bit chunk of the 256-bit internal XKEY Data Structure.

### 39.3.10 Oscillator Counter Control Register (RNG\_OCCR)

This register cannot be accessed when the RNGB is in the Secure Mode. The register is used to tell the oscillator test logic how long to count the oscillator clock pulses. The value written to the register is decremented every system clock cycle (ipg\_clk) until it reaches zero. When it reaches zero, the Oscillator Counter register is frozen allowing an outside observer to count the number of oscillator clock pulses in a given amount of time. In turn, the approximate frequency of each oscillator clock can be computed.

Address: 21B\_4000h base + 28h offset = 21B\_4028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### RNG\_OCCR field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–0 OCCR	Reading the number of clock cycles remaining; Writing number of clock cycles during which to count the oscillator clock pulses

### 39.3.11 Oscillator Counter (RNG\_OSC\_CNT)

This register can only be accessed when the RNGB is in Control Access Mode. The register is used to count the number of oscillator pulses received from Oscillator starting from the time the RNGB Oscillator Counter Control Register is written and ending at the time the RNGB Oscillator Counter Control Register reaches zero. The Oscillator Counter resets when the RNGB Oscillator Counter Control Register is written to and stops incrementing when the RNGB Oscillator Counter Control Register reaches zero. This register is clocked asynchronously with respect to the ipg\_clk clock domain. In order to avoid unknown values during simulation and meta stable states in silicon, this register should only be read when the RNGB Oscillator Counter Control Register is zero (i.e. when the register is not counting).

Address: 21B\_4000h base + 2Ch offset = 21B\_402Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

### RNG\_OSC\_CNT field descriptions

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–0 CLOCK_ PULSES	CLOCK PULSES

### 39.3.12 Oscillator Counter Status (RNG\_OSC\_CNT\_STAT)

This register can only be accessed when the RNGB is in the Control Access Mode. The bits in this register signal that each oscillator has generated a minimum of 0x400 clock pulses each. After hardware reset, the oscillator counters count oscillator pulses for 0x1000 system clock cycles. So, immediately after reset, the bits in this register verify that the oscillators are running at least 1/4 the frequency of the system clock. This information may be useful on the tester where deterministic behavior is required.

Address: 21B\_4000h base + 30h offset = 21B\_4030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0															OS
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### RNG\_OSC\_CNT\_STAT field descriptions

Field	Description
31–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 OS	Oscillator Status  Indicates that the clock derived from the oscillator has toggled at least 0x400 times since the last write of the Oscillator Counter Control Register (the act of resetting the RNGB can be considered such a write since the Oscillator Counter Control Register resets to a non zero value).  0 Oscillator has not toggled 0x400 times. 1 Oscillator has toggled 0x400 times.

## 39.4 Functional Description

The RNGB performs two functional operations, seed generation and random number generation.

These operations, described in [Modes of Operation](#), are performed in conjunction with the major functional blocks in the RNGB described below.

### 39.4.1 Pseudorandom Number Generator (PRNG)

The PRNG implements the NIST-approved PRNG described in the *Digital Signature Standard*. The 160-bit output of the SHA-1 block is the next five words of random data. The PRNG is designed to generate  $2^{20}$  words of random data before requiring reseeding, using the TRNG only during the seeding/initialization process. The initial seed takes approximately two million clock cycles. After this the RNGB can generate five 32-bit words every 112 clock cycles. Reseeding takes place transparently through use of the simultaneous reseed LFSRs. The entropy stored in this 128-bit LFSR and 128-bit shift register is added directly into the XKEY structure via the RNGB XSEED generator whenever reseeding is required.

### 39.4.2 True Random Number Generator (TRNG)

The TRNG is comprised of two entropy sources each providing a single bit of output. Concatenated together, these two output bits are expected to provide one bit of entropy every 100 clock cycles. In addition to generating entropy, the TRNG also performs several statistical tests on its output. The pass/fail status of these tests are reflected in RNG\_ESR.

### 39.4.3 Resets

There are two ways to reset the RNGB: power-on/hardware reset and software reset. The software reset is functionally equivalent to the power-on/hardware reset. The power-on/hardware reset is asynchronous. Software reset is performed by setting the RNG\_CMD[SR] bit. These are summarized in the table below.

**Table 39-14. Reset Summary**

Reset	Source	Characteristics	Internally resets:	Affect on External Signal:
Hardware	ipg_hard_async_reset_b	Active-low, asynchronous, minimum 1-cycle	All interface registers and puts RNGB into the IDLE state	—
Software	RNG_CMD[SR]	Active-high	All interface registers and puts RNGB into the IDLE state	—

### 39.4.3.1 Power-on/Hardware Reset

Asserting the ipg\_hard\_async\_reset\_b signal sets all interface registers to their default state and puts the state machine into the IDLE mode.

### 39.4.3.2 Software Reset

The software reset is functionally equivalent to the hardware reset, but allows the RNGB to be fully reset by writing to the SW\_RST bit (bit-6) in the RNGB Command Register. This bit is self-resetting. A software reset may be performed at any time.

## 39.4.4 RNG Interrupts

There is a single RNG interrupt generated to the processor's interrupt controller. The source of the interrupt is determined by reading the RNG status register. If an error is the cause of the interrupt, further information is available by reading the RNG error status register. The interrupts can be masked by the RNG\_CR[MASKDONE or MASKERR] bits

It is strongly recommended that the error interrupt is only masked while debugging, since masking the error interrupt could hide potentially fatal errors or conditions that could result in corrupted results. All errors are considered fatal, requiring the RNG to be reset. The RNG does not service any random data until a reset occurs.

The available interrupt sources are described in the following table.

**Table 39-15. RNG Interrupt Sources**

Sources	Status Bit Field	RNG_CR Mask Bit Field	Description
Seed generation done	RNG_SR[SDN]	MASKDONE	First seed was generated
Self test done	RNG_SR[STDN]	MASKDONE	Self test finished
Error	RNG_SR[ERR]	MASKERR	Error detected. See RNG_ESR for details.
Linear feedback shift register (LFSR)	RNG_ESR[LSFRE]	MASKERR	Fault in one of the TRNG's LFSRs
Oscillator	RNG_ESR[OSCE]	MASKERR	TRNG ring oscillator may be malfunctioning
Self test	RNG_ESR[STE]	MASKERR	Self test failed
Statistical test	RNG_ESR[SATE]	MASKERR	Statistics test for last seed generation failed
FIFO Underflow	RNG_ESR[FUFE]	MASKERR	FIFO read while empty

## 39.5 Initialization/Application Information

Information found here describes the module initialization.

### 39.5.1 Manual Seeding

The intended general operation of the RNGB is as follows:

1. Reset/initialize.
2. Write to the RNG\_CR to setup the RNGB for the desired functionality.
3. Write to RNG\_CMD to run self-test or seed generation.
4. Wait for interrupt to indicate completion of the requested operation(s).
5. Repeat steps 3–4 if seed generation is not complete.
6. Poll RNG\_SR for FIFO level.
7. Read available random data from output FIFO.
8. Repeat steps 6 and 7 as needed, until  $2^{20}$  words have been generated.
9. Write to RNG\_CMD to run seed mode.
10. Repeat steps 4–9.

### 39.5.2 Automatic Seeding

The intended general operation of the RNGB with automatic seeding enabled is as follows:

1. Reset/initialize.
2. Write to the RNG\_CR to setup the RNGB for automatic seeding and the desired functionality.
3. Wait for interrupt to indicate completion of first seed
4. Poll RNG\_SR for FIFO level.
5. Read available random data from output FIFO.
6. Repeat steps 4 and 5 as needed. Automatic seeding occurs when necessary and is transparent to operation.

### 39.5.3 Deterministic Mode

This section provides a simple example of how to use the RNGB in deterministic mode. For this process to work, the system must be in a non-secure state.

1. Reset / Initialize RNGB
2. Write to Control Register (bit-8) to Enable Deterministic Mode (System Must not be Secure)
3. Follow steps 2-5 of [Manual Seeding](#) or 2-7 of [Automatic Seeding](#)

### 39.5.4 Oscillator Frequency Verification

This section provides a simple example of how to use the RNGB in deterministic mode. This test will allow an approximate determination of the oscillator frequency. In order for this process to work, the system must be in a non-secure state.

1. Reset / Initialize RNGB
2. Write to Control Register (bit-9) to Enable Control Access (System Must not be in the Secure State)

3. Write to the Verification Control Register (bit-2) to enable the TRNG Oscillator Frequency Test
4. Write to the Oscillator Counter Control Register, the number of system clocks (Nsys), required for the test
5. Poll the Oscillator Counter Control Register till 0 is read.
6. Read the number of oscillator clock cycles (Nosc) from the Oscillator Counter Register. From the system clock frequency (fsys), the number of system clocks used and the number of oscillator clock cycles read (Nosc) an approximate frequency (fosc) of the TRNG oscillator can be calculated as follows:
  - a. Test period =  $T_p$
  - b.  $T_p = N_{sys} / f_{sys}$
  - c. TRNG oscillator period =  $T_{osc}$

  - e. TRNG Oscillator frequency =  $1 / T_{osc}$

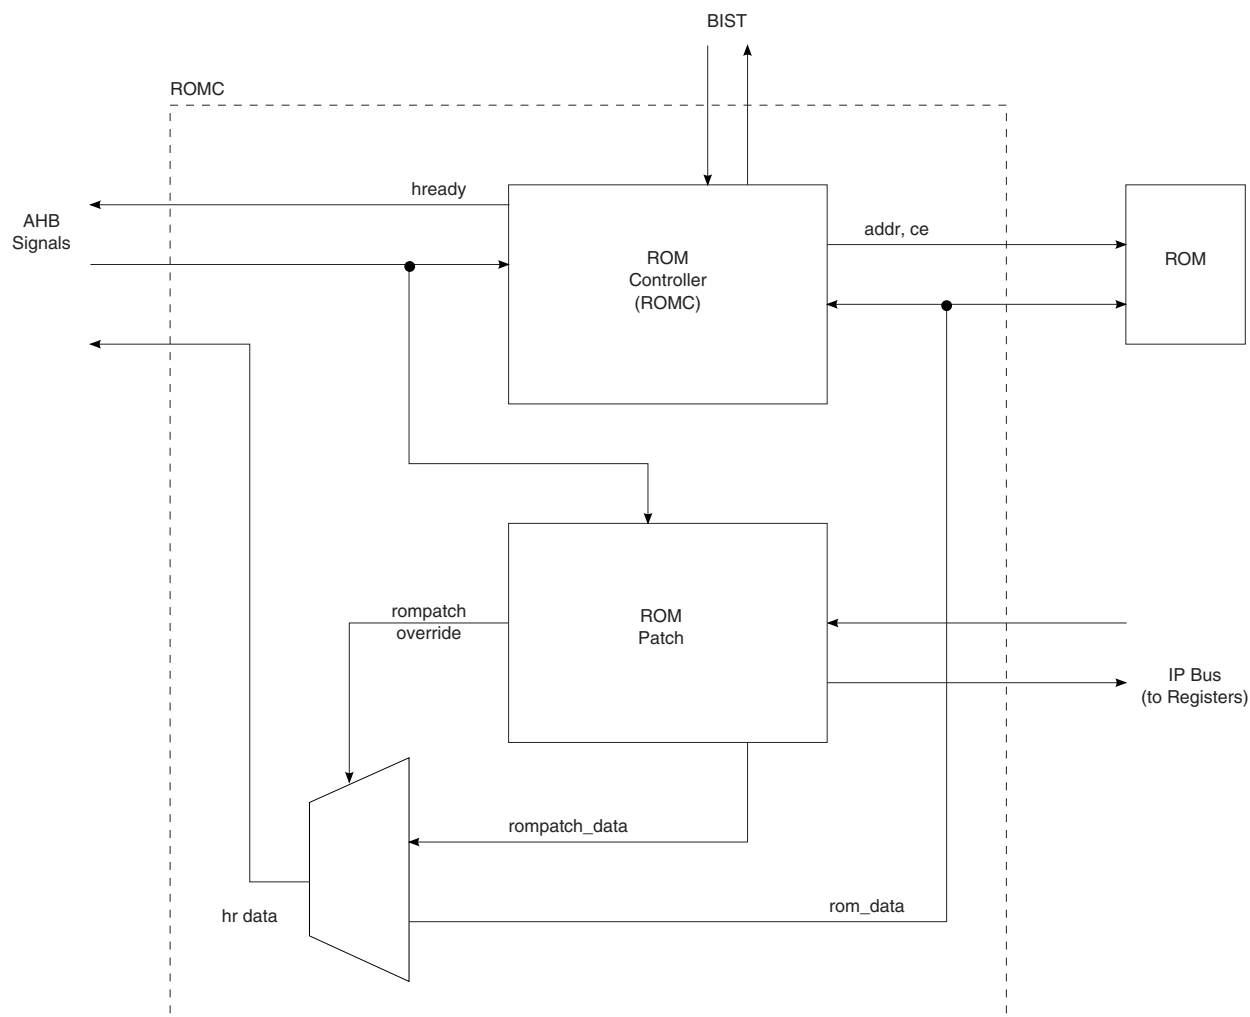

## **Chapter 40**

# **ROM Controller with Patch (ROMC)**

### **40.1 Overview**

The Read Only Memory Controller with ROM Patch (ROMC) acts as an interface between the ARM advanced high-performance bus (AHB - Lite) and the Read Only Memory. The ROMC consists of a ROM Controller and a ROM Patch. The ROM Patch is used to either patch code routines or fix data tables in the ROM area. There is an IP Bus interface to access the ROM Patch Registers and. The figure below depicts the main functional sub-blocks of the ROMC.

**Figure 40-1. ROMC Block Diagram**

### 40.1.1 Features

- Supports ROM size ranges from 16 Kbyte up to 4 Mbyte with increments of 1 Kbyte
- Supports opcode patching for a maximum of 16 different addresses in 4 Mbytes of ROM space
- Supports one-word data fixes for a max of 8 memory locations in 4 Mbytes of ROM space
- Supports patching of the Reset Vector (at 0x0000\_0000) to allow external booting

### 40.1.2 Modes of Operation

There are two modes of operation: normal mode and BIST mode.

In normal mode (`ipt_bist_en = 0`), the ROMC ensures correct reads from the ROM, assuming the memory complies with the characteristics and requirements for which the ROMC was designed.

### 40.1.2.1 Low Power Mode

There are two clock enables that are used to switch off parts of the ROMC logic when inactive. The first clock enable is used to disable the ROM Controller when the master connected to the AHB interface is not initiating a read to the ROM. The second clock enable is used to disable the registers used to program the ROM patch feature when the registers are not being accessed.

## 40.2 Clocks

The table found here describes the clock sources for ROMCP.

Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information.

**Table 40-1. ROMCP Clocks**

Clock name	Clock Root	Description
hclk	ahb_clk_root	System / bus clock
hclk_reg	ipg_clk_root	System access clock
96krom_CLK	ahb_clk_root	ROM clock

## 40.3 Memory Map

### 40.3.1 ROM Memory Map in detail

The ROMC supports ROM sizes with a range of 16 Kbyte to 4 Mbyte with an increment of 1 Kbyte. The 16 Kbyte lower limit was chosen because the minimum size of security code on an ARM platform is approximately 16 Kbyte of code, which is only accessible in supervisor mode. Note that it is the MMU that controls whether any region of memory is secure.

The exception vectors must be secured as well, and must be put in the same area as the security code. Since they must reside at address 0x0000\_0000, the entire 16 Kbyte of ROM which can only be accessible in supervisor mode is located at the very beginning of the platform memory map.

If the user chooses not to use the security code, a memory size smaller than 16 Kbyte can be connected to the platform (minimum of 1 Kbyte). The MMU can be programmed to allow any kind of access into this memory. However, if the ROM size is less than 16 Kbyte, memory aliasing will occur for all invalid addresses greater than the memory size but within the 16 Kbyte of space.

For ROM sizes bigger than 16 Kbyte, the rest of its physical size resides at the address starting at 0x0040\_4000 (4 M+16 Kbyte) going up to [0x0040\_4000 + (mem. size - 16Kbyte)]. For examples on power-of-two memories please see [Figure 1](#).

## **40.4 Functional Description**

This section is divided up into the ROM Controller Functional Description and the ROMC functional description.

### **40.4.1 ROM Controller (ROMC) Functional Description**

#### **40.4.1.1 Functionality overview**

The ROMC serves two main functions. First, as an interface between the AHB-Lite bus on an ARM platform and the ROM. Second, it drives and receives several signals for the BIST engine. In normal mode of operation, the ROMC monitors the AHB-Lite for memory access requests and performs the memory operation to the ROM.

The ROMC includes the option to wait state all accesses from either the ARM or non-ARM masters to ROM in the event that timing requirements will not allow single hclk clock cycle reads. If a wait state is required, the static inputs rom\_wait\_arm or rom\_wait\_alt\_mstr can be set to 1 and accesses will take two hclk clock cycles. If wait states are not required, rom\_wait\_arm or rom\_wait\_alt\_mstr can be set to 0 and accesses will take one hclk clock cycle to complete.

### **40.4.2 ROMC Functional Description**

### 40.4.2.1 ROMC Disabling

All the bits in the ROMC\_ROMPATCHENL register are cleared on Reset, disabling all the address comparators. Once the comparators have been enabled, the ROMC functions of data fixing and opcode patching can be quickly disabled by setting the DIS bit in the ROMC\_ROMPATCHCNTL register. This bit is used to enable secure operations in which patching functions need to be disabled. This bit is cleared on Reset.

### 40.4.2.2 ROMC Event Priority

The ROMC has a total of 16 address comparators. The first 8 (0 through 7) comparators can be programmed for the data fixing function (through the 8 data fix enable bits in the ROMC\_ROMPATCHCNTL register) while the rest are for opcode patching by default. This allows for potential multiple matching events involving both data fixing and opcode patch types. In these cases the ROMC assigns the highest priority to a data fixing event.

For example, if the ROMC is set up to data fix a certain address with comparator 4 and also opcode patch the same address with comparator 7, it will let comparator 4 have higher priority in indicating a match, and data from ROMC\_ROMPATCHD4 will be put on the rompatch\_romc\_hrdata bus as the override value.

If multiple address matches of the same type level occur concurrently, then the ROMC will choose the source number based on the one with the highest source number. For example, the ROMC is setup to data fix the same location with address comparators 4 and 7, then address comparator 7 will have higher priority in indicating a match, and the value from ROMC\_ROMPATCHD7 will be put on the rompatch\_romc\_hrdata bus as the override value. The same priority applies for an opcode patch event, except the override data is in the form of an SWI instruction with the comment field set to the source number with the highest priority.

### 40.4.2.3 Data Fixing

The data fixing feature allows ROM data to be updated by direct replacement when it is being read. This data usually originates from data tables, but can include ARM instructions. To enable data fixing on a certain address, this address value is written in to one of the first eight (0 through 7) of ROMC\_ROMPATCHAxx registers and the same numbered bit set in the ROMC\_ROMPATCHENL and ROMC\_ROMPATCHCNTL registers. The data to be used for replacement is placed in the corresponding ROMC\_ROMPATCHDxx.

The ROMC looks for a read access to ROM (either code fetch or data load) by snooping the AHB interface for read transactions. The address is compared with the values stored in the ROMC\_ROMPATCHAxx[22:2] registers. If a match occurs from one of the comparators, the ROMC places the value in the corresponding ROMC\_ROMPATCHDxx register on the read data bus by overriding the read data coming from the actual ROM (see the mux in [Figure 40-1](#)). The value on the read data bus is maintained until hready is asserted to terminate the access. In data fixing, the entire word is replaced so if a byte or half-word access occurs on a "data fix" location, the entire data word is replaced. The word being replaced is word aligned. (The two LSBs of the matching ROMC\_ROMPATCHAxx are ignored in the data fix operation.)

#### 40.4.2.4 Opcode Patching

The opcode patch feature provides the ARM core a mechanism to fetch updated versions of code routines that were originally programmed in ROM. This patching mechanism makes use of the SWI (software interrupt instruction) and a table of function pointers residing in writable memory. The opcode being patched is replaced with a SWI instruction by the ROMC. Subsequent processing of the SWI reads from a function pointers table to obtain the address of the replacement code. Execution resumes with this code patch.

To enable opcode patching of a certain address, this address value is written into one of the ROMPATCHAxx registers and the corresponding bit set in the ROMPATCHENL to enable the associated comparator. The register's LSB (ROMC\_ROMPATCHxx[0]) should be set if THUMB mode patching is in effect for this address. The ROMC identifies a ROM read access by snooping the AHB interface. The address is compared with the values stored in the ROMC\_ROMPATCHAxx[22:2] registers. If a match occurs from one of the comparators, the ROMC generates the opcode of a software interrupt (SWI) instruction with the comment field containing the number of the matching address comparator. This opcode and comment is placed on the read data bus until hready is asserted by the ROM controller to terminate the read access.

The type of SWI generated, (that is, either ARM or THUMB), is determined by the LSB of the ROMC\_ROMPATCHAxx register associated with the opcode patch. This bit is cleared for ARM mode (32 bits). The ROMC generates a 32-bit SWI (opcode field is 0xEF, occupying bits [31:24] of the word), with the least significant 5 bits of the 24-bit comment field (bits [23:0]) containing the number of the matching address comparator. The rest of the comment field is filled with zeros. This means that the ROMC will use 16 of the 16777216 possible software interrupts. The ROMC overrides the read data from the ROM.

If the LSB of the matching ROMC\_ROMPATCHAxx register is set, the opcode patch is in THUMB mode (16 bits or half word). The ROMC generates a 16-bit SWI instruction (opcode field is 0xDF, occupying bits [15:8] of the half word) with the least significant 5 bits of the 8-bit comment field containing with the source number of the address comparator. The rest of the comments field is filled with zeros. This means that the ROMC will use 16 of the 256 possible software interrupts. The ROMC puts this 16 bit SWI instruction value on the proper half of the rompatch\_romc\_hrdata bus. The other half is zeroed out. Which half of the bus contains the SWI opcode and comment depends on the mode (Big Endian or Little Endian) and the bit 1 of the matching ROMC\_ROMPATCHAxx register. In Little Endian mode, the lower half is bits {15:0} and the upper half is bits {31:16}. The order is reversed in Big Endian mode.

In Little Endian mode (bigend signal negated), if bit 1 of the matching ROMC\_ROMPATCHAxx is cleared (lower half word selected) then the SWI instruction is put on the lower 16 bits of the read data bus and the upper 16 bits are zeroed out. Only the lower 16 bits of the read data bus is overwritten by the ROMC data. If ROMC\_ROMPATCHAxx[1] is set (upper half word selected), the SWI instruction is put on the upper 16 bits of the read data bus and the lower 16 bits are zeroed out. Only the upper 16 bits of the read data bus is overwritten.

In Big Endian mode (bigend asserted), if bit 1 of the matching ROMC\_ROMPATCHAxx is cleared (lower half word selected) then the SWI instruction is put on the upper 16 bits of the read data bus while the lower 16 bits are zeroed out. Only the upper 16 bits of the read data bus is overwritten. If ROMC\_ROMPATCHAxx[1] is set (upper word selected), the SWI instruction is put on the lower 16 bits and the upper 16 bits are zeroed out. Only the lower 16 bits of the read data bus is overwritten.

The eventual execution of the SWI causes the ARM to save the CPSR in SPSR\_SVC, the address of the next instruction after the SWI in R14\_SVC, enter Supervisor mode, and fetch the SWI vector at 0x8, which then takes it to a handler for further processing as described in the next section.

#### 40.4.2.4.1 Typical Software Response to Opcode Patch

When the SWI handler executes it needs to determine whether the SWI was generated by the ROMC. This is done by loading the SWI instruction and extracting its comment field. The state of the ARM core (ARM or THUMB) when the SWI was executed dictates whether to load the instruction word (ARM) or half word (THUMB). This state information can be determined by testing the T bit (bit 5) of the SPSR. If it's set, the execution was in THUMB mode.

By convention, if the comment field of the SWI is greater than 16, the software interrupt was initiated by software (i.e. an operating system call), and a branch is taken to the appropriate handler routine for further processing. If the comment field is less than 16, the SWI was generated by the ROMC performing a code patch operation. In this case, the software then reads from a table of function pointers, using the value in the SWI comment field as the index into the table. The value that is read is the address of the code patch. This value is loaded into the PC to begin the execution of the code patch. The following code segment illustrates a typical handling of the SWI.

```

stmfd      sp!, {r0-r1,lr}      @ push register onto SWI stack
mrs        r0, spsr             @ get saved status register
tst        r0, #0x20            @ check if call was in THUMB mode
ldrneh     r0, [lr,#-2]         @ yes: load opcode half-word and
bicne      r0, r0, #0xff00      @ yes: extract THUMB comment
ldreq      r0, [lr,#-4]         @ no: load opcode word and
biceq      r0, r0, #0xff000000  @ no: extract ARM comment
                                @ now r0 has comment field
cmp        r0, #16              @ compare to 16 (maximum for ROMC)
ldrlt      lr, =rompatch_tbl_ptr @ < 16: get top of current ROMC
                                @ table; global variable which is
                                @ changeable per context
ldrlt      r1, [lr, r0, lsl #2] @ < 16: read function pointer from
                                @ table assumed an array of pointers
                                @ patch functions
strlt      r1, [sp, #8]         @ < 16: store function pointer onto
                                @ stack in position of link register
ldmpltfd   sp!, {r0-r1,pc}^     @ < 16: "fake" return from SWI, will
                                @ vector core to appropriate patch
                                @ function and set core back to previous
                                @ mode of operating
ldr        r1, =swi_hdlr       @ >= 16: pointer to standard SWI
                                @ handler
mov        lr, pc               @ >= 16: set link register
bx         r1                   @ >= 16: jump to standard SWI
                                @ handler
ldmfd      sp!, {r0-r1,pc}^     @ >= 16: pop registers from stack

```

#### 40.4.2.5 External Boot Feature

Following a Reset event, the ARM issues an instruction fetch of the Reset Vector from address 0x0. This instruction, normally residing in ROM is usually a branch to a Reset handler or boot code which also normally resides in ROM. The ROMC external boot feature allows the bypassing of this code, using a different boot code residing perhaps in external memory.

This feature uses the data fix mechanism and works as follows: if the boot\_int signal is negated when a Reset event occurred, the ROMC will perform a data fix of the Reset Vector at 0x0 with the following instruction (opcode 0xE59FF00C):

```

ldr        pc, [pc, #12]        @ read 0x0000_0014 for reset_vector

```

The value of PC when this instruction is executed is 8 so that a PC relative offset of 12 makes the source address 20 or 0x14. When this instruction executes, the ARM core reads from address 0x0000\_0014, triggering a ROMC data fix operation which places the

value taken from the external boot address on the read data bus, with the two LSBs zeroed out. This value is returned to the ARM to be placed in the PC causing code fetch and execution to start from that address.

#### 40.4.2.6 Alternate Masters and ROMC

The ROMC sits on the AHB bus of the internal ROM (ROMC). This means that the ROMC can modify values on the read data bus going to the master. Therefore, any master which reads an opcode patched or data patched location will read patched data.

### 40.5 ROMCP Memory Map/Register Definition

All registers are accessible through an IP Bus and can only be accessed in privileged mode. These registers can only be written with 32-bits stores and are clocked by hclk\_reg.

The ROMC register placement was originated from the AWPT design used in the ARM7 platform of Neptune

## 40.5.1 ROMC Data Registers (ROMC\_ROMPATCHnD)

The ROMC data registers (ROMC\_ROMPATCHD7 through ROMC\_ROMPATCHD0) store the data to use for the 8 1-word data fix events. Each register is associated with an address comparator (7 through 0). When a data fixing event occurs, the value in the data register corresponding to the comparator that has the address match is put on the romc\_hrdata[31:0] bus until romc\_hready is asserted by the ROM controller to terminate the access. A MUX external to the ROMC will select this data over that of romc\_hrdata[31:0] in returning read data to the ARM core. The selection is done with the control bus rompatch\_romc\_hrdata\_ovr[1:0] with both bits asserted by the ROMC.

If more than one address comparators match, the highest-numbered one takes precedence, and the value in corresponding data register is used for the patching event.

## ROMC\_ROMPATCHnD field descriptions

Field	Description
31–0 DATAx	Data Fix Registers - Stores the data used for 1-word data fix operations. The values stored within these registers do not affect the writes to the memory system. They are selected over the read data from ROM when a data fix event occurs.

**ROMC\_ROMPATCHnD field descriptions (continued)**

Field	Description
	If any part of the 1-word data fix is read, then the entire word is replaced. Therefore, a byte or half-word read will cause the ROMC to replace the entire word. The word is word address aligned.

**40.5.2 ROMC Control Register (ROMC\_ROMPATCHCNTL)**

The ROMC control register (ROMC\_ROMPATCHCNTL) contains the block disable bit and the data fix enable bits. The block disable bit provides a means to disable the ROMC data fix and opcode patching functions, even when the address comparators are enabled. The External Boot feature is not affected by this bit. The eight data fix enable bits (0 through 7), when set, assign the associated address comparators to data fix operations

**NOTE**

Bits 27 and 22 always read as 1s.

Address: 21A\_C000h base + F4h offset = 21A\_C0F4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

**ROMC\_ROMPATCHCNTL field descriptions**

Field	Description
31–30 -	This field is reserved. Reserved
29 DIS	ROMC Disable -- This bit, when set, disables all ROMC operations. This bit is used to enable secure operations.  0 Does not affect any ROMC functions (default) 1 Disable all ROMC functions: data fixing, and opcode patching
28–8 -	This field is reserved. Reserved
7–0 DATAFIX	<b>Data Fix Enable - Controls the use of the first 8 address comparators for 1-word data fix or for code patch routine.</b>  0 Address comparator triggers a opcode patch 1 Address comparator triggers a data fix

### 40.5.3 ROMC Enable Register High (ROMC\_ROMPATCHENH)

The ROMC enable register high (ROMC\_ROMPATCHENH) and ROMC enable register low (ROMC\_ROMPATCHENL) control whether or not the associated address comparator can trigger a opcode patch or data fix event. This implementation of the ROMC only has 16 comparators, therefore ROMC\_ROMPATCHENH and the upper half of ROMC\_ROMPATCHENL are read-only. ROMC\_ROMPATCHENL[15:0] are associated with comparators 15 through 0. ROMC\_ROMPATCHENLH[31:0] would have been associated with comparators 63 through 32.

Address: 21A\_C000h base + F8h offset = 21A\_C0F8h

ROMC\_ROMPATCHENH field descriptions

Field	Description
31–0 -	This field is reserved. Reserved

### 40.5.4 ROMC Enable Register Low (ROMC\_ROMPATCHENL)

The ROMC enable register high (ROMC\_ROMPATCHENH) and ROMC enable register low (ROMC\_ROMPATCHENL) control whether or not the associated address comparator can trigger a opcode patch or data fix event. This implementation of the ROMC only has 16 comparators, therefore ROMC\_ROMPATCHENH and the upper half of ROMC\_ROMPATCHENL are read-only. ROMC\_ROMPATCHENL[15:0] are associated with comparators 15 through 0. ROMC\_ROMPATCHENLH[31:0] would have been associated with comparators 63 through 32.

Address: 21A\_C000h base + FCh offset = 21A\_C0FCh

**ROMC\_ROMPATCHENL field descriptions**

Field	Description
31–16 Reserved	This field is reserved.
15–0 ENABLE	<b>Enable Address Comparator</b> - This bit enables the corresponding address comparator to trigger an event.  0 Address comparator disabled 1 Address comparator enabled, ROMC will trigger a opcode patch or data fix event upon matching of the associated address

**40.5.5 ROMC Address Registers (ROMC\_ROMPATCHnA)**

The ROMC address registers (ROMC\_ROMPATCHA0 through ROMC\_ROMPATCHA15) store the memory addresses where opcode patching begins and data fixing occurs. The address registers ROMC\_ROMPATCHA0 through ROMC\_ROMPATCHA15 are each 21 bits wide and dedicated to one 4 Mbyte memory space. Bits 21 through 2 are address bits, to be compared with romc\_haddr[21:2] for a match; bit 1 is also an address bit used for half word selection. Bit 0 is the mode bit (set to 1 for THUMB mode). 1-word data fixing can only be used on the first 8 of the address comparators. ROMC\_ROMPATCHA0 through ROMC\_ROMPATCHA15 are associated each with address comparators 0 through 15.

Address: 21A\_C000h base + 100h offset + (4d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

# Chapter 41

## Smart Direct Memory Access Controller (SDMA)

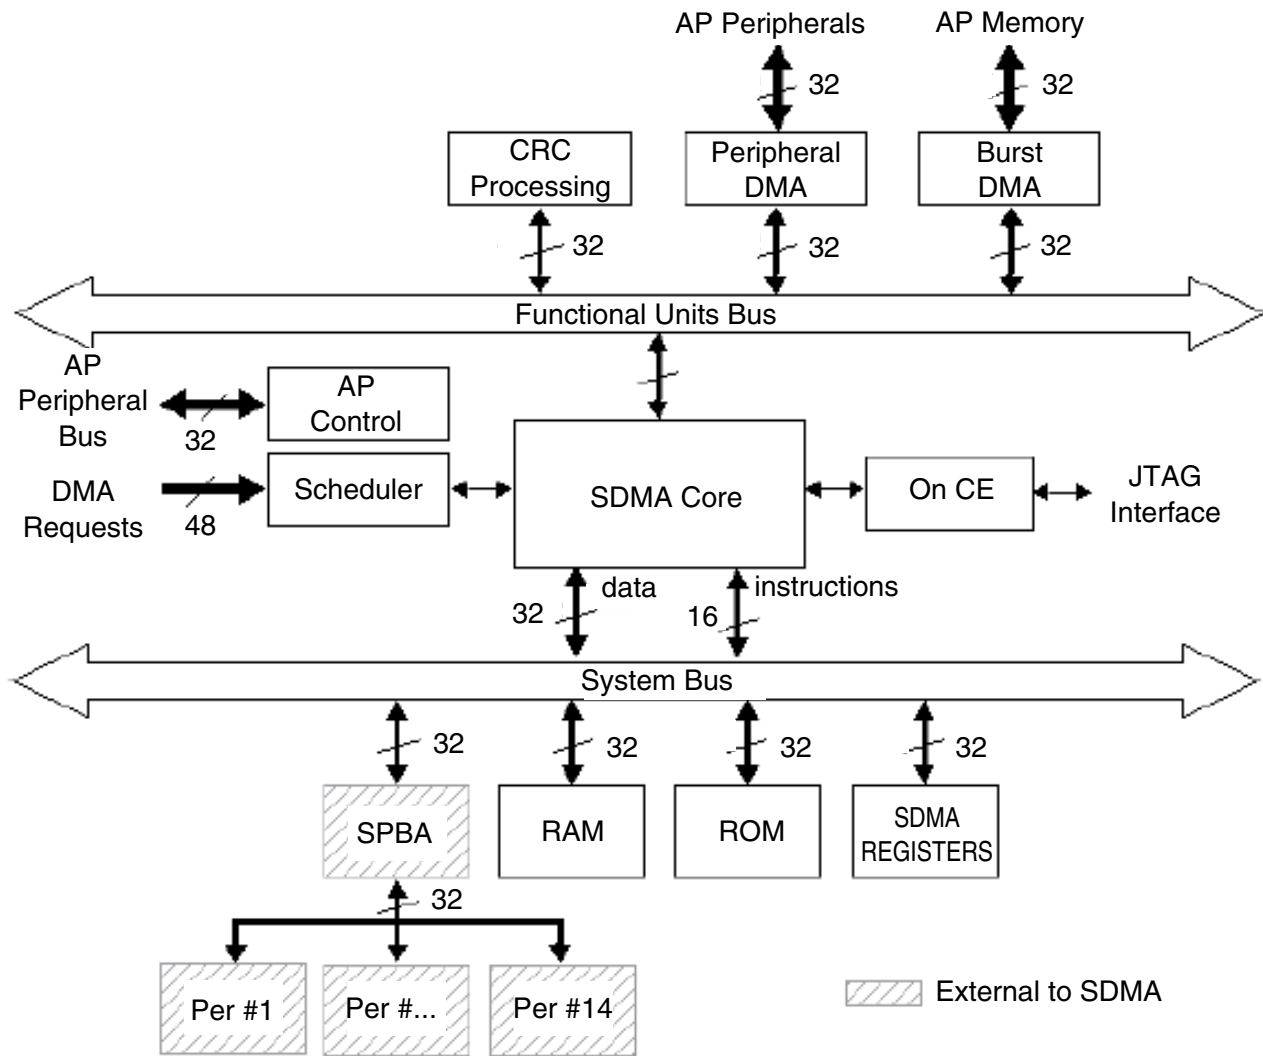

### 41.1 Overview

The Smart Direct Memory Access (SDMA) controller offers highly-competitive DMA features combined with software-based virtual-DMA flexibility. It enables data transfers between peripheral I/O devices and internal/external memories.

The SDMA controller helps maximize system performance by off-loading the ARM core in dynamic data routing.

#### 41.1.1 Block Diagram

The figure below shows a block diagram of the SDMA controller. It includes the custom RISC core along with its RAM, ROM, DMA units, and the scheduler.

**Figure 41-1. SDMA Block Diagram**

The SDMA core executes short routines that perform DMA transfers; these routines are called *scripts*. The SDMA core interfaces to its own memory via the SDMA system bus. The SDMA system bus supports a 32-bit data path and a 16-bit address bus. The system bus datapath is used for both 16-bit instruction (program) memory access and 32-bit data access. DMA units interface to the core via the Functional Unit Bus and use dedicated registers to perform DMA transfers.

The SDMA memory contains a ROM and a RAM. The ROM contains startup scripts (for example, boot code) and other common utilities, which are referenced by the scripts that reside in the RAM. The internal RAM is divided into a context area and a script area (more details about this mapping are available in [Instruction Memory Map](#) and [Data Memory Map](#)).

Every transfer channel requires one context area to keep the contents of all the core and unit registers while inactive. Channel scripts are downloaded into the internal RAM by the SDMA using a dedicated channel that is started during the boot sequence. Downloads are invoked using commands and pointers provided by the ARM platform. Every channel contains a corresponding channel script located in RAM and/or ROM that can be reconfigured independently as-needed. Channel scripts can be stored in an external memory and downloaded when needed. The SDMA can be configured with any mixture of scripts to enable an endless combination of supported services.

The scheduler monitors and detects DMA requests, mapping them to channels, and mapping individual channels to a pre-configured priority. At any given point, the scheduler presents the highest priority channel that requires service to the SDMA core. A special SDMA core instruction is used to "conditionally yield" the current channel being executed to an eligible channel that requires service. If (and only if) there is an eligible channel pending, will the current channel execution be preempted.

There are two yield instructions that differently determine the eligible channels: In the first version, eligible channels are pending channels with a strictly higher priority than the current channel priority. In the second version (yieldge), eligible channels are pending channels with a priority that is greater or equal to the current channel priority. The scheduler detects devices that need service through its 48 DMA request inputs. After a request is detected, the scheduler determines the channel(s) that is (are) triggered by this request and marks it (them) as pending in the "Channel Pending (EP)" register. The priorities of all the pending channels are continuously evaluated in order to update the highest pending priority. The channel pending flag is cleared by the channel script when the transfer has completed.

The ARM platform control block contains the control registers used to configure the 32 individual channels. There are 48 Channel Enable registers, and every register maps one DMA request to any desired combination of channels. The 32 Priority registers are used to assign a programmable 1-of-7 level priority to every possible channel. This block also contains all other control registers that the ARM platform can access.

The 48 DMA requests that are connected to the scheduler come from a variety of sources. The "receive register full" and "transmit register empty" signals found in the UART and USB ports are typical examples of DMA requests that can be connected to the SDMA. These requests can be used to trigger a specific SDMA channel, or several channels.

There is an OnCE compatible debug port for product development. The OnCE includes support for setting breakpoints, single-step and trace, and register dump capability. In addition, all memory locations are accessible from the debug port.

## 41.1.2 Features

The following are the SDMA features:

- Multi-channel DMA supporting up to 32 time-division multiplexed DMA channels
- Hardware or software driven triggers for each channel
- 48 hardware driven triggers that can be mapped to any channel.
- Memory accesses including linear addressing, FIFO addressing and 2D addressing
- Fast context-switching with two-level, priority-based preemptive multi-tasking
- 16-bit instruction-set micro-RISC engine (the SDMA core)
- Two DMA units with some or all the following features:
  - Auto-flush and prefetch capability
  - Flexible address management (increment, decrement, and no address changes on source and destination address)
  - Misaligned data-transfer support
  - Uni-directional and bi-directional flows (copy mode)
  - Up to eight-word buffers for configurable burst transfers
- Support of byte-swapping
- An available API and library of scripts
- Little-Endian and Big-Endian modes
- Hardware handshakes for low-power entry sequence
- Security support to lock contents of the SDMA script RAM.
- 4-Kbyte ROM containing startup scripts (for example, boot code) and other common utilities that can be referenced by RAM-located scripts
- 8-Kbyte RAM area is divided into a processor context area and a code space area used to store channel scripts that are downloaded from the system memory
- Debug support, including a OnCE port, real-time monitors, and embedded cross-trigger events
- Supported clock frequencies in process:
  - Configurable clock options for the SDMA core and the ARM platform DMA units
    - 1:2 ratio with maximum of SDMA core running at ARM platform Peripheral Bus speed and DMA running at max DMA frequency.
    - 1:1 ratio when both SDMA core and ARM platform DMA clocks are set to the ARM platform Peripheral Bus speed.
- Peripheral bus interface for configuration register programming by the ARM platform
- The SDMA RISC engine (arithmetic and logic operations), which is referred to as the "SDMA core."
- An internal peripheral bus connected to the Shared Peripherals Bus Interface (SPBA) that enables access to up to 14 shared peripherals. SDMA supports 32-bit accesses to word peripherals and 16-bit accesses to half-word peripherals.

- The peripheral DMA unit that is hooked-up to the ARM platform Crossbar Switch to service ARM peripherals
- The burst DMA unit is able to perform burst accesses to the external memory
- All the DMA units are 32-bit AHB masters. They are connected to different buses, thus allowing concurrent accesses.

## 41.2 External Signals

The table found here describes the external signals of SDMA.

**Table 41-1. SDMA External Signals**

Signal	Description	Pad	Mode	Direction
SDMA_EXT_EVENT0	Event 0 signal	ECSPI2_MISO	ALT1	I
SDMA_EXT_EVENT1	Event 1 signal	ECSPI2_MOSI	ALT1	I

## 41.3 Clocks

The table found here describes the clock sources for SDMA

. Please see [Clock Controller Module \(CCM\)](#) for clock setting, configuration and gating information. For functional information regarding module clocks, see [SDMA Clocks and Low Power Modes](#).

**Table 41-2. SDMA Clocks**

Clock name	Clock Root	Description
events_sync_clk (clk)	ahb_clk_root	ARM peripheral / events clock
ips_hostctrl_clk	ipg_clk_root	Host control clock
ap_ahb_clk	ahb_clk_root	ARM platform bus clock
core_clk	ipg_clk_root	Module / Core clock
tck	-	JTAG access clock

## 41.4 Functional Description

The figure below shows the SDMA topology, and is composed of the following components:

## Functional Description

- SDMA Core ([SDMA Core](#))
- SDMA Scheduler ([Scheduler](#))
- Functional Units:
  - Burst DMA ([Burst DMA Unit](#))
  - Peripheral DMA ([Peripheral DMA Unit](#))
- ARM platform Control for ARM control register access.
- Internal RAM and ROM Memory ([SDMA Programming Model](#))
- OnCE debug Port ([The OnCE Controller](#))

The functional unit bus provides access by the SDMA core to the DMA units. The system bus provides access to SDMA internal memory and also supports up to 14 peripherals.

Figure 41-2. SDMA Connections

## 41.4.1 SDMA Core

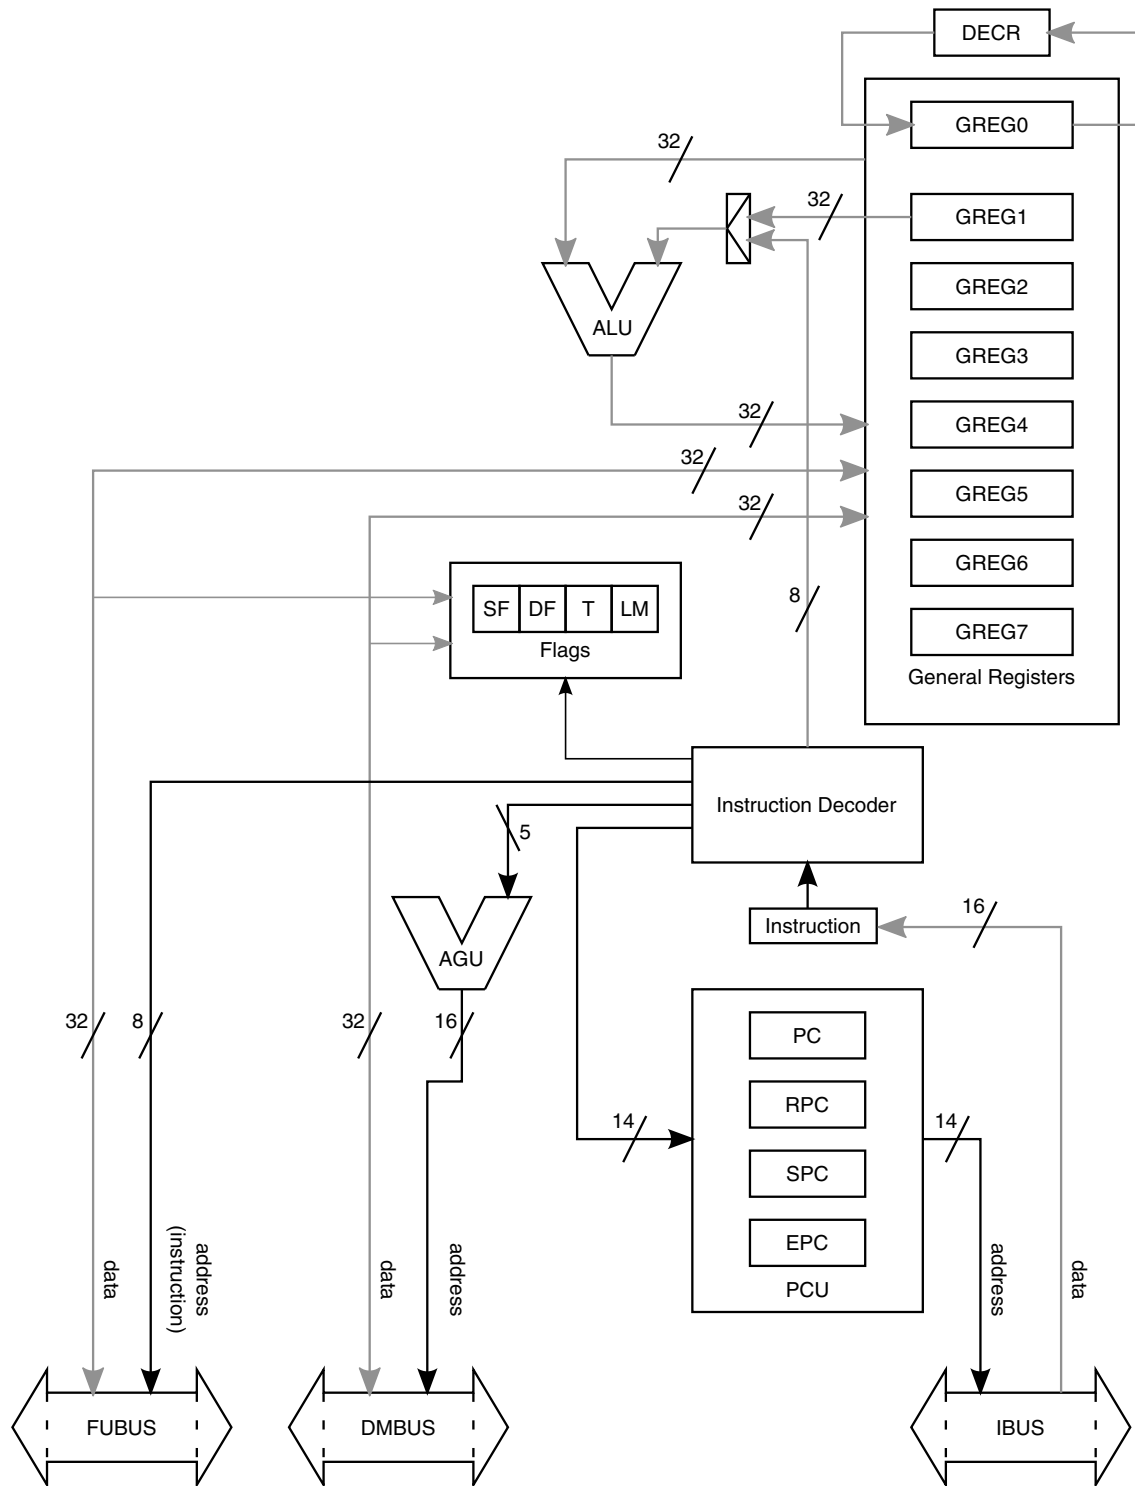

The SDMA core is a customized RISC-like processor that is specifically developed to control DMA units and perform L1 tasks like byte-stuffing or framing.

The SDMA core incorporates on-chip debug capability using the OnCE.

The SDMA core is based on a 32-bit register architecture with 16-bit instructions. There are eight general purpose 32-bit registers, four flags (T, LM, SF, and DF), and four PCU registers (PC, RPC, SPC, and EPC) that can address 16,384 16-bit instructions.

### 41.4.1.1 SDMA Core Structure

The figure found here shows the structure of the SDMA core. It also shows the different registers, calculation resources, and possible data movements.

**Figure 41-3. SDMA Core**

- The Program Control Unit (PCU) is described in [Program Control Unit \(PCU\)](#). It handles the state of the core and generates the instruction fetch addresses. Instructions are retrieved from the Instruction Bus (IBUS) and stored in the SDMA

core instruction register prior to their decoding. The PCU contains the following registers:

- The Program Counter (PC) contains the address of the current instruction.
- The Return Program Counter (RPC) contains the address of the instruction that follows a jump to the subroutine.
- The Start Program Counter (SPC) contains the address of the first instruction of the current hardware loop.
- End Program Counter (EPC) contains the address of the last instruction of the current hardware loop.
- The other core registers are the general purpose registers (GREGn) and the flags.
  - The general purpose registers can be used to hold data and addresses. They can be loaded with immediate values (for example, 8-bit data that are encoded in the instruction), results of calculations that were performed with the ALU, 32-bit data that comes from the memory or peripherals via the Data Memory Bus (DMBUS), 32-bit data that comes from the DMAs via the Functional Units Bus (FUBUS) or another general purpose register. Their content can be the operands of the ALU, the data to send on either bus (DMBUS or FUBUS), or a pointer to memory (DMBUS address).
  - The general register 0 (GREG0) is also the hardware loop counter. In hardware loops, it cannot be used for any other purpose. This register uses a dedicated decrement unit (DECR) shown in [Figure 41-3](#).
  - The flags reflect the status of operations:
    - SF and DF are set when the last load or store on either bus (FUBUS or DMBUS) received an error response.
    - LM is set when the core is executing instructions inside a hardware loop.
    - T is set when the ALU operation result was 0 or the loop counter reaches 0 (the latter is preponderant when an ALU operation is the last instruction of a hardware loop).
- The ALU has two operands: any general register and either a second general register or an immediate value. The result is always stored into the first general register. A NOP function can be utilized by moving a register's contents into itself (For example, the instruction: mov R0,R0).
- The 16-bit instructions are fetched via the instruction bus (IBUS) whose address is driven by the PC. The SDMA RAM and ROM are visible to the core as 16-bit devices through this interface.
- The memory (RAM and ROM), memory mapped registers, and external peripherals are accessed via the DMBUS. The address is always taken from a general register whose content is added to a 5-bit immediate value. This is the only available addressing mode. The DMBUS is a 32-bit data bus. Except for the peripherals that

are external to the SDMA, the address accuracy is the 32-bit word (for example, adding 1 to an address points to the next word, not the next byte).

- The functional units are accessed via the FUBUS connection. The data is exchanged with any general register, but the address (which in fact is the instruction and the selector of the functional unit) comes from an 8-bit field of the corresponding load or store.

### 41.4.1.2 Program Control Unit (PCU)

This part of the SDMA core is dedicated to the control of the RISC engine, as implied by the instructions that are executed. Its behavior is determined by the instruction type and the inputs of the SDMA.

It contains the PC, RPC, SPC, and EPC registers that are described in [SDMA Core Structure](#).

#### 41.4.1.2.1 Instruction Types

The state sequence and the delay of execution vary according to the type of the instruction. There are six possible categories of instructions, as follows:

1. Standard: Most of the instructions belong to this category, and always last 1 cycle.
2. ldf/stf: These are respectively the load and store instructions that access the functional units. They last  $1+n$  cycles where  $n$  is the number of wait-states of the targeted functional unit.
3. ld/st: These are the load and store instructions that access the memory and peripherals. They last  $1+n$  cycles where  $n$  is the number of wait-states of the targeted device (1 for the ROM, RAM, and memory mapped registers, 1 + the external peripheral wait-states). These instructions always last at least two cycles, but the core is able to handle them in one cycle. The first wait-state is inserted outside the core.
4. Branch: These are all the instructions that cause the Program Counter to point to another instruction other than the following one (for example, one that breaks the sequential flow). There are the absolute jumps, the conditional branches, the jump to the sub-routines, and the return from the sub-routine.
5. Loop, Modified Load or Store: The hardware loop instruction modifies the potential behavior of any load or store inside the loop (for example, when the LM flag is set). A jump may be implied after any such load or store if it received an error. The error causes an early exit of the loop, which means a jump to the instruction that follows the one that is pointed to by EPC. An additional cycle is required by the PCU to perform the jump (+1 to the ld/st/ldf/stf original execution delay). Although there is

usually an implicit jump after the last instruction of the loop when the PC goes back to SPC, this is performed at no cycle cost.

6. Done: The done, yield, or yieldge instructions are used to control channel switching. When no channel switching is performed, these instructions last a single cycle. When there is a change of channel or context switch, the delay is variable and depends on many factors (as detailed in [Context Switching](#)).

#### 41.4.1.2.2 PCU States

The PCU state is visible through outputs of the SDMA (see [Real-Time Debug Outputs](#)) or the OnCE status register(see [OnCE Status Register \(OSTAT\)](#)).

The PCU state is a four-bit field that can take the values shown in the following table. [Figure 41-4](#) shows the possible state transitions and the corresponding conditions.

**Table 41-3. PCU States**

Value	State	Description
0	Program	This is the usual instruction cycle.
1	Data	This state is inserted when there are wait-states during a load or a store on the data bus (ld/st type).
2	Change of Flow	This is the second cycle of any instruction that breaks the sequence of instructions (branch and done types). This state lasts only a single cycle; it is always followed by the Program state.
3	Error in Loop	This state is used when an error causes a hardware loop exit (loop-modified load or store type). This state only lasts a single cycle; it is always followed by the Program state.
4	Debug	The SDMA is stopped in debug mode.
5	Functional Unit	This state is inserted when there are wait-states during a load or a store on the functional units bus (ldf/stf type).
6	Sleep	No script is running: The core is idle after saving the last channel context.
7	Save	The context switch FSM is saving the current channel.
8	Program in Sleep	Same as Program except there is no associated channel, this state is used when instructions are executed after entering debug mode, whereas the core was in either Sleep mode.
9	Data in Sleep	This is the same as Data except there is no associated channel.
10	Change of Flow in Sleep	This is the same as Change of Flow except there is no associated channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
11	Error in Loop in Sleep	This is the same as Error in Loop except there is no associated. channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
12	Debug in Sleep	This is the same as Debug except the core was put in debug mode when no channel was active.
13	Functional Unit in Sleep	This is the same as Functional Unit except there is no associated channel.

*Table continues on the next page...*

**Table 41-3. PCU States (continued)**

Value	State	Description
14	Sleep after Reset	This shows that no script is running, and the core is idle after a reset. When a channel becomes active, no context is restored but the core starts its boot program located at address 0 (or the address available in register in <a href="#">Channel 0 Boot Address (SDMAARM_CHN0ADDR)</a> ).
15	Restore	The context switch FSM is restoring the next channel context.

Figure 41-4. PCU State Diagram

### 41.4.1.3 SDMA Core Memory

The SDMA has two memory spaces: one for the instructions and one for the data. As both spaces share the same resources (ROM and RAM devices), the system bus manages possible conflicts when the core accesses the same resource for both an instruction read and a data read or write.

Program and data memory is further described in [Address Space](#).

Instructions of 16-bit width are stored in 32-bit wide devices and can be accessed as data. The mapping is Big Endian: an even instruction address (terminated by 0) accesses the most significant part of the 32-bit data (bits [31:16]), and an odd instruction address (terminated by 1) accesses the least significant part of the 32-bit data (bits [15:0]). Instructions can be fetched out of internal ROM or RAM.

Data can be read from ROM, RAM, memory mapped registers, and external peripherals, and written to the same devices (except the ROM).

The ROM contains bootload scripts, channel scripts, and common subroutines which may be referenced by channel scripts elsewhere in the ROM or RAM.

The RAM is divided into a context area and a code space area which may be used to store channel scripts. The RAM contains undefined values after a hardware reset. Channel scripts and initial context values are downloaded into RAM using channel 0 which is reserved for bootload functions.

## 41.4.2 Scheduler

All channel scheduling hardware is included in the Scheduler.

### 41.4.2.1 Primary Functions

The scheduler is a hardware-based design used to coordinate the timely execution of 32 virtual DMA channels by the SDMA core on the basis of channel status and priority.

The scheduler performs the following functions:

- Monitors, detects, and registers the occurrence of any one of the 48 DMA requests
- Links a specific request to a channel or group of channels (channel mapping)
- Ignores requests that are not mapped to a previously configured channel
- Maintains a list of all the channels that are requesting service

- Assigns a pre-programmed priority level (1 of 7) to every channel requesting service
- Detects and flags overrun/underrun conditions

### 41.4.2.2 Channels and DMA Requests

#### 41.4.2.2.1 Channels

A Virtual Channel (hereafter simply called a channel) manages a flow of data through the SDMA. Flows are typically unidirectional.

The SDMA can have up to 32 simultaneously operating channels, numbered from 0 to 31. Channel 0 is usually dedicated to control the SDMA script downloading. All the channels can be assigned by the ARM platform software.

#### 41.4.2.2.2 DMA Requests

A DMA request is caused by externally (for example, external to the SDMA) controlled conditions (for example, UART receive FIFO reaches a threshold). The SDMA currently supports up to 48 DMA requests.

#### 41.4.2.2.3 Mapping from DMA Requests to Channels and Priorities

A channel can stall waiting on a single DMA request. A single DMA request can awake more than one channel (in fact, any request can awake any combination of channels).

The mapping between DMA requests and channels is program-controlled. There is a storage element assigned for each of the 48 requests that contains a bitmap table of the channels that are awakened by the event.

Every channel also has a three-bit register that indicates its priority.

### 41.4.2.3 Scheduler Functional Description

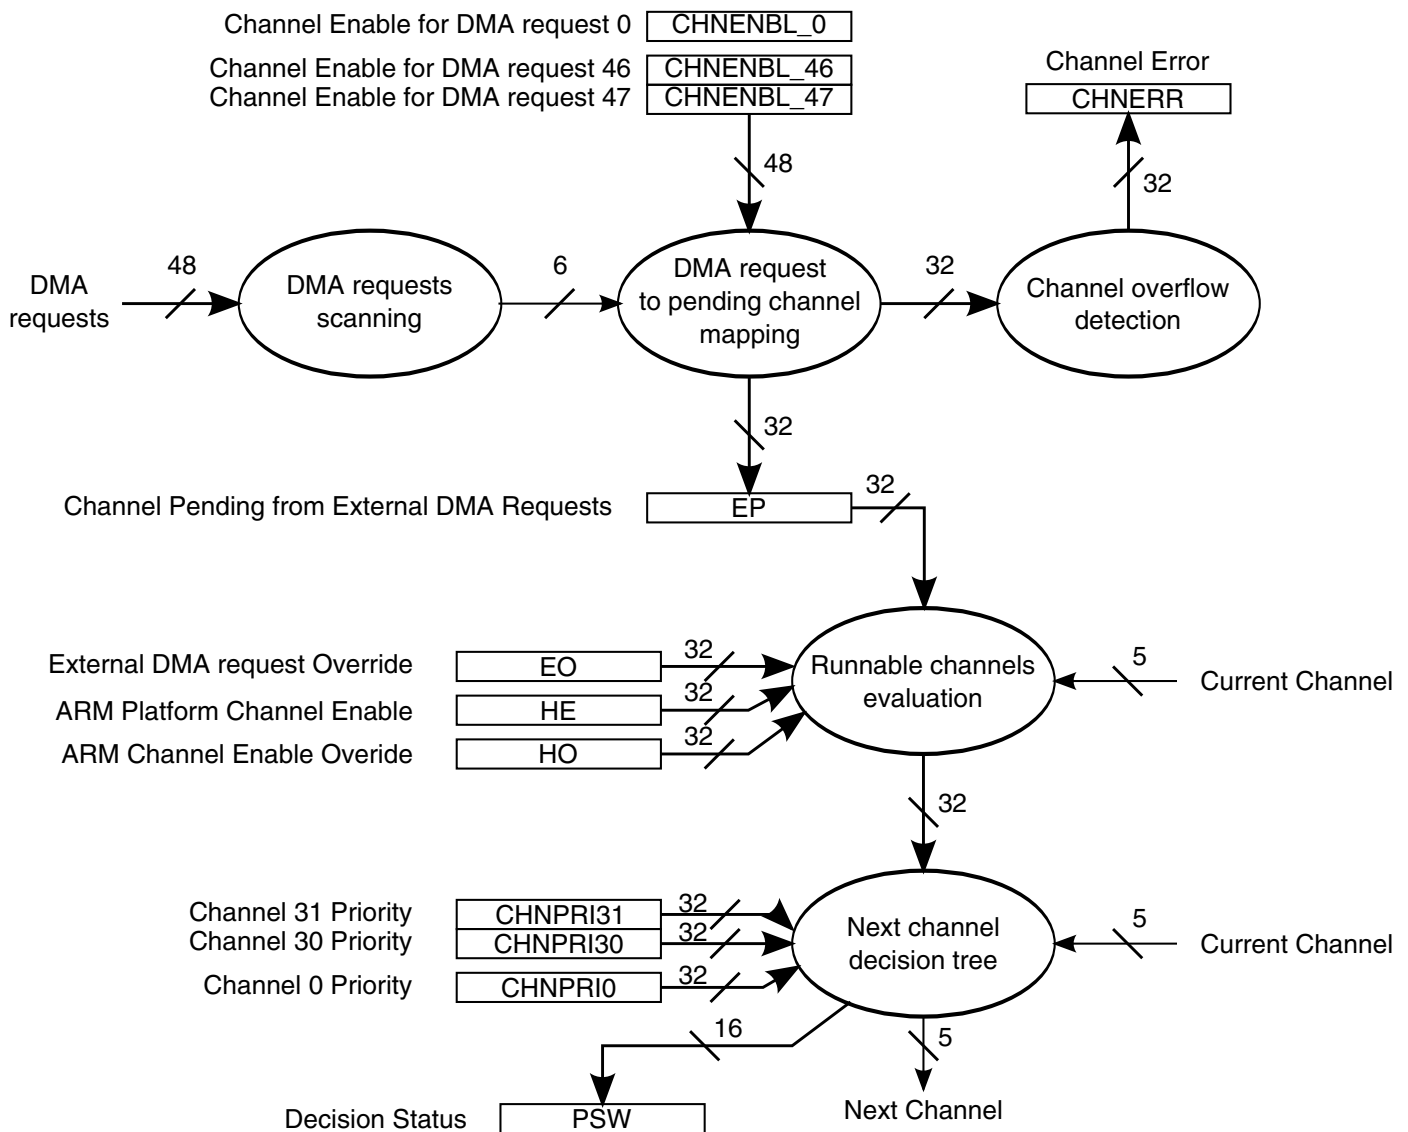

[Scheduler Overview](#) describes the behavior of the SDMA scheduler-from the channel enabling conditions to the highest priority pending channel selection.

### 41.4.2.3.1 Scheduler Overview

The scheduler algorithm is built in hardware. It is provided with possibilities for the ARM platform to control its behavior.

The scheduler processes incoming DMA requests, maps detected requests to 0, one, or several channels, maintains a list of channels that are requesting service (pending channels), identifies the top priority and its associated channel, and selects the next active channel when the current channel yields.

The following figure shows a functional overview.

**Figure 41-5. SDMA Hardware Scheduler**

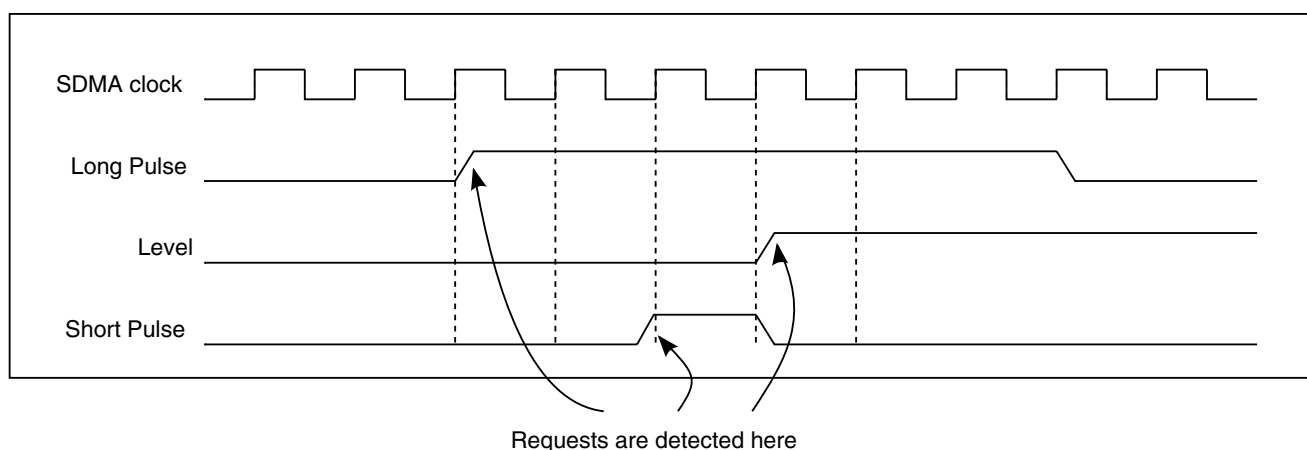

### 41.4.2.3.2 DMA Requests Scanning

The scheduler contains a 48-bit edge detection device that detects the rising edge of every DMA request and transmits the request number to the next stage.

The DMA requests are assumed to be generated on the same reference clock as the SDMA core clock; they are detected as soon as the signal goes from a 1-to-n-cycles low state to a 1-to-m-cycles high state.

This system is able to detect single-cycle pulses as well as level-based DMA requests such as a FIFO threshold crossing. In this case, the SDMA provides a memory mapped register that can be used by the channel script to monitor the DMA requests lines, and thus determines whether the data transfer is done or not done, and then continues with the transfer or closes the channel.

When several DMA requests are detected at the same time, they are forwarded to the next scheduler stage at the rate of one request per cycle. No request is lost.

**Figure 41-6. Examples of Valid DMA Requests**

The DMA request inputs are connected to various sources that depend on the SoC. The exact list of DMA request inputs and their associated number is available in each respective project-specific chapter.

### 41.4.2.3.3 Mapping DMA Requests to Pending Channels

Whenever a DMA request is detected by the first stage, its number is used in the second stage to determine the channels that have to be activated.

This is performed with an array of 48 registers that are 32 bits wide: There are 48 Channel Enable Registers (CHNENBLn), one register per DMA request. The DMA request number selects the Channel Enable Registers, and every bit of this 32-bit register indicates that the corresponding channel must be activated when it is a 1.

This information is passed on the EP register. For every bit of the Channel Enable Register that is set, the corresponding bit of the EP register is also set, and the remaining bits of EP are left unchanged. The transformation of EP is summarized by the following equation:

$$EP = EP \text{ or } CHNENBLn$$

The EP register is used to know which channels require service because they received a DMA request.

Typical contents of the CHNENBLn registers are all 0s, except for a single bit set. For example, a DMA request triggers one channel, but all 0s or several 1s are possible. One DMA request could activate several channels, and the channel execution sequence can be controlled by the channel priorities and numbers, as explained in the next sections. The following table illustrates an example configuration.

### NOTE

From the table, the DMA request 0 is programmed to simultaneously trigger channels 0, 1, and 31. Also, DMA requests 30-47 are not used in this example. The remaining channels 2 to 30, are configured to be triggered by DMA requests 29 to 1, respectively.

**Table 41-4. Channel Enable RAM Programming Example**

DMA Request Number	Channel																															
	31																															0
0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

**Table 41-4. Channel Enable RAM Programming Example (continued)**

DMA Request Number	Channel																															
	3 1																															0
44	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
45	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
46	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
47	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### 41.4.2.3.4 Channel Overflow

A channel overflow occurs when a DMA request requires service from channel  $n$  by setting bit  $n$  of the register EP, but this bit is already set, meaning channel  $n$  is already pending. This can come from an overrun/underrun condition.

This detection is possible only when the DMA requests are pulses, because a level-based DMA request stays high until it is serviced, even though an underrun or overrun condition occurs, thus preventing another edge detection of the DMA request.

The channel overflow information is saved in the 32-bit CHNERR register (1 bit per channel). You can configure the SDMA to trigger an interrupt to the ARM platform when there are 1s in CHNERR. Every bit of CHNERR is masked with the corresponding bit of INTRMASK and if it gives a 1, the corresponding bit of INTR is set, triggering the interrupt.

#### 41.4.2.3.5 Runnable Channels Evaluation

The EP register is used in conjunction with several other 32-bit registers to determine the channels that are runnable.

Registers EO, DO, HO and HE, are controlled by the ARM platform. EP is controlled by the DMA requests and their mapping to channels.

Several channels may be runnable at any given time. The  $i^{\text{th}}$  channel is runnable if (and only if) the condition below is true:

$(\text{HE}[i] \text{ or } \text{HO}[i]) \text{ and } (\text{DO}[i]) \text{ and } (\text{EP}[i] \text{ or } \text{EO}[i])$

After reset, the HE[i], HO[i], EP[i], and EO[i] bits are all cleared whereas the DO[i] bits are all set. The functions associated with DO are not available for this device. When DO[i] is set, the scheduler condition becomes:

(HE[i] or HO[i]) and (EP[i] or EO[i])

The registers in these equations are controlled as follows:

- ARM platform (host) channel enable flag HE[i] may be set or cleared by the ARM platform with the HSTART and STOP\_STAT registers. It can also be cleared by the i<sup>th</sup> channel script.

Typical usage is for the ARM platform to set this flag to activate the channel. The flag is cleared by the SDMA core when the transfer is done.

- Externally triggered channel pending flag EP[i] is set by the scheduler when the channel was activated by a DMA request. It can be cleared by the i<sup>th</sup> channel script.
- The ARM platform channel override flag HO[i] may be set or cleared by the ARM platform. When set, it enables the i<sup>th</sup> channel to run without the involvement of the ARM platform.

Typical usage is for the ARM platform to set this flag for channels that do not need ARM platform supervision such as channels that are controlled by DMA request events (EP).

- DO should always be set to 1 so that the runnable channel evaluation considers only HO, HE, EP, and EO.
- Externally triggered channel override flag EO[i] may be set or cleared by the ARM platform. When set, it prevents the i<sup>th</sup> channel from stopping and stalling on incoming peripheral DMA requests. This is the case when the channel is not handling data transfers with peripherals (for example, a memory to memory transfer).

The SDMA can clear the HE[i], and EP[i] bits by means of a done or notify instruction. The done instruction causes a reschedule; thus, enabling another channel to preempt the current one, while the notify instruction does not. The done and notify instructions can clear either HE[i] or EP[i] (never more than one at a time).

**Table 41-5. Runnable Channel Selection Control**

Register	Set by	Cleared By
HO	Write to HOSTOVR register	Write to HOSTOVR register
HE	Write to HSTART register	Write to STOP_STAT register or by the channel script with the done or notify instructions.
DO	Write to DSPOVR register	Write to DSPOVR register
EO	Write to EVTOVER register	Write to EVTOVER register
EP	Set by external DMA request event input.	By the channel script with the done or notify instructions

#### 41.4.2.3.6 Next Channel Decision Tree

The next channel number is computed from the runnable channels list, the current channel number, and their respective priorities.

It is re-evaluated every cycle, but is only used when the current channel yields or terminates by executing a yield, yieldge, or done instruction.

The decision tree is based on the selection of the runnable channel that has the highest priority.

The highest priority channel is selected according to the following rules:

- Runnable channels are sorted by priority.
- If one of the channels with the highest priority had been preempted by a channel with a higher priority, but did not want to yield to a channel of the same priority (for example, it executed a yield, not a yieldge), it is elected as the next channel.
- The channels that belong to the highest priority group are sorted by their number and the channel that has the highest number in this group becomes the next channel. For example, if priorities are the same, channel 31 will be selected before channel 30.

When the current channel requires a reschedule with a yield(ge) or a done instruction, the context switch decision is based on the instruction parameter, the current channel number and priority, and the next channel number and priority. The possible cases are all listed in the following table. The grayed cells correspond to unusual cases that should not occur with a typical usage of the SDMA.

**Table 41-6. Channel Switching Decision with a yield, yield(ge), or done**

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
yield (done 0)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Current
			Current < Next	Next <sup>1</sup>
	Not runnable	Not runnable	none	none <sup>2</sup> (occurs when the channel was disabled by the ARM platform)
	Not runnable	Runnable	none	Next <sup>1</sup> (occurs when the channel was disabled by the ARM platform)

*Table continues on the next page...*

**Table 41-6. Channel Switching Decision with a yield, yield(ge), or done (continued)**

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
yieldge (done 1)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Next <sup>1</sup>
			Current < Next	Next <sup>1</sup>
	Not runnable	Not runnable	none	none <sup>2</sup> (occurs when the channel was disabled by the ARM platform)
	Not runnable	Runnable	none	Next <sup>1</sup> (occurs when the channel was disabled by the ARM platform)
done (done>1)	Not runnable	Not runnable	none	none <sup>2</sup>
	Runnable	Not runnable	none	Current <sup>3</sup> (occurs when the done instruction does not disable the channel runnable condition)
	Not runnable	Runnable	none	Next <sup>1</sup>
	Runnable	Runnable	none	Current <sup>3</sup> (occurs when the done instruction does not disable the channel runnable condition)

1. Current channel script execution is stopped, its context is saved; the next channel context is restored and its script execution resumes
2. Current channel context is saved and SDMA enters IDLE mode
3. Current channel context is saved, then restored, and the current channel script resumes execution

Finally, when the SDMA is in IDLE mode and a runnable channel is elected as the next channel, its context is immediately restored and the script execution resumes.

The *combinatorial-decision* tree supports dynamic modifications of the EP, EO, HE, HO, and DO flags as well as dynamic modifications of the channel priorities. The propagation times are detailed in [Scheduler Pipeline Timing Diagram](#).

The decision tree status is available in the PSW register, which is continuously updated. It contains the next channel priority, the next channel number, the current channel priority, and the current channel number. When a priority is read as 0, it means the channel is not runnable.

A few examples of decisions are presented below:

- Channel 31 is running with priority 5, channels 13 and 24 are pending with the same priority 5; channel 24 is eligible as the next channel since  $24 > 13$ .
- Channel 31 is running with priority 7, channels 13 and 24 are pending with priority 5; channel 31 is the next channel because its priority is greater than the other pending channels.

- Channels 7, 23, and 29 are pending with the same priority. Channel 7 is active and runs a yieldge; it is preempted by channel 29. After a period of time, channel 29 runs a yieldge, it is then preempted by channel 23 that is the selected channel since channel 29 is the current channel. Later, channel 23 runs a yieldge and is preempted by channel 29. Channels 23 and 29 will go on switching after every yieldge until one of them terminates. It is only at that point that channel 7 becomes eligible again.
- Channel 11 is running with priority 3, and channel 15 is pending with priority 4. When the channel 31 script executes a yield instruction, it gets preempted by channel 15; then channels 6 and 18 with priority 3 become pending. Because channel 11 was preempted after executing a yield and there is no pending channel with a strictly greater priority, it is eligible as the next channel (although its number  $11 < 18$ ).

#### 41.4.2.3.7 Scheduler State Diagram

The [Figure 41-7](#) summarizes the behavior of the SDMA scheduler with details about the exact mechanism of the priority decision tree. It is important to understand the scheduler is a hardwired pipeline, which means all the stages are performed simultaneously every cycle, but a change on any given stage is reflected on the next stage after the delays presented in [Scheduler Pipeline Timing Diagram](#).

Figure 41-7. Scheduler State Diagram

#### 41.4.2.3.8 Scheduler Pipeline Timing Diagram

The SDMA scheduler process of DMA-request and control-register modifications is not immediate.

The figure below shows the exact delays of all the tasks. The reference clock is the SDMA core clock.

**Figure 41-8. Scheduler Timing Diagram**

Two numbers can be inferred from this timing diagram. First, it takes six SDMA core clock cycles to update the next channel from a DMA request. Second, it takes three SDMA core clock cycles to update the next channel from a direct modification of the condition registers (EP, DO, HE, or HO) by any processor. The processors that can modify these bits include SDMA with a done instruction or the ARM platform with a write access through the corresponding control port on their respective peripheral bus).

#### 41.4.2.3.9 Channel-DMA Request Mapping

The 48 DMA request inputs to the SDMA scheduler are listed in project-specific chapters. Refer to the respective chapters for this information.

#### 41.4.2.3.10 Examples: How to Start a Channel

A channel can be started when the following equation is true for channel  $i$ :

$(HE[i] \text{ or } HO[i]) \text{ and } (DO[i]) \text{ and } (EP[i] \text{ or } EO[i])$

Once this equation is true, the scheduler can start this channel according to the priority of all pending channels. Several examples of configuration are listed below:

1. To start a channel triggered by ARM platform software:
  - Initially, configure  $HO[i]=0$ ,  $DO[i]=1$ , and  $EO[i]=1$  using registers indicated in [Table 41-5](#).
  - ARM platform software triggers the channel by writing to the HSTART register to set  $HE[i]=1$ , thereby setting the above equation true.
2. To start a channel triggered by DMA request event.
  - Initially, configure  $HO[i]=1$ ,  $DO[i]=1$ , and  $EO[i]=0$  using registers indicated in [Table 41-5](#).
  - The DMA request is asserted to trigger the channel by setting  $EP[i]=1$ , which makes the above equation true.

#### 41.4.2.4 Context Switching

On execution of a done or yield(ge) instruction, the current channel may be changed either because it has finished (which necessarily happens when the done instruction is executed), or it was preempted by a higher priority channel (which is possible but not systematic when the yield(ge) is executed).

Upon a channel change the SDMA goes through a context switch procedure.

When the current channel yields or ends, the context for that channel is saved into the context RAM locations for that channel. When the next channel starts running, its context is first restored from RAM.

Since context RAM is not yet initialized by reset, there will be no context restore at the beginning of the first channel (bootload channel) run after reset. It is expected that the bootload channel will be used to initialize the context for all other channels. When the bootload channel finishes running or yields, SDMA will enter its SAVE state and save that channel's context into RAM. Then, if the bootload channel is called again later, the context will be restored from RAM when the channel starts again.

The context structure for each channel is defined in [Context Switching-Programming](#) and [Table 41-11](#). There will be one context area reserved for each channel. When a channel ends or yields, the SDMA core registers are automatically saved into the context RAM and later restored from the context RAM when the channel is next run. The total RAM space reserved for 32-channel contexts is either 3K or 4K depending on whether the SMSZ bit is set in the CHN0ADDR register, which enables an additional 8 words of scratch RAM for each context.

#### 41.4.2.4.1 Context Switch Modes

The exact procedure to save the context of the old channel, and to restore the context of the new channel depends on the context switch mode selected by the ARM platform in the CONFIG control register.

The following are the context switch modes:

- By default, the "dynamic" context switch is set. This mode provides the most efficient context switch for an average of eight cycles to stop the current channel, save its context, restore the next channel context, and resume its execution. It consists of saving modified registers of the current channel in the background (for example, during the channel execution)-which leaves very few registers to save when the switch is decided-resuming execution of the next channel as soon as possible (for example, when the minimal set of registers is restored), and continuing the restore phase during this execution.
- In "dynamic with no loop" mode, the same principle is followed except the modified registers are only saved in the background when the loop flag is not set. This mode offers almost the same effectiveness as the previous one, but it prevents the system from accessing the RAM during loops to save power. This is the recommended mode for an efficient context-switch when the loop bodies are short.
- In "dynamic power" mode, no background saving is performed, which reduces power consumption to the minimum. The modified registers are only saved when the context switch starts. The restore phase is the same as before. This is the mode that achieves the optimal power consumption at the cost of a slower context-switch.
- In a "static" context switch, all the registers are saved when a context switch is decided, and all the registers are restored before starting the execution of the new channel. This mode enables a predictable behavior of the context switch since all the registers are restored prior to the channel start and all registers are saved after the channel termination.

#### NOTE

Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized during the context SAVE phase when the channel is done or yields. Subsequent calls to the same channel or different channels may use any of the dynamic context modes. This will ensure that all context locations for the bootloader channel are initialized, and prevent undefined values in context RAM from being loaded during the context restore if the channel is re-started later.

#### 41.4.2.4.2 Context Switch Procedure

The Program Control Unit goes into the *save* state, the current context is spilled into memory, and the next channel context is restored according to the context-switch mode that was selected by the ARM platform.

The context switch procedure is as follows:

1. Load the current context's spill base address.
2. Spill the modified registers of the current channel to memory according to the selected context switch mode while the channel is running.

On a done or yield(ge) that causes the channel preemption, the PCU goes into the *save* state. In *static* mode, all the registers are saved; whereas, in either *dynamic* mode, the registers that were modified but not yet saved are then saved, and the PCU registers and flags are finally saved.

3. Put the SDMA core into *sleep* and wait for new channels to be serviced. This step is skipped if there are pending channels when the current channel is saved.

As soon as there is at least one pending channel, the PCU goes into its *restore* state to restore the context of the channel that was elected by the scheduler.

Once a channel is elected, it remains the current channel until its script requests a rescheduling operation with a done or yield(ge) instruction. That means the current channel cannot be modified by the ARM platform, even if it is no more runnable or if its priority is modified.

The ARM platform can however force a reschedule by writing the corresponding bit in the CONFIG register, which has the same effect as if the script had executed a done instruction. That feature should only be used to stop the SDMA in emergency cases.

4. Load the context base-address of the new channel.

In "static" mode, all the registers are restored. In either "dynamic" modes, only the PCU registers are restored.

The new channel is running. In "static" mode, no more activity regarding context restoring or saving is performed. In either "dynamic" modes, the registers are restored in the background every time an access to the context RAM is possible, and priority is given to restoring the registers that are required by the next instruction to be executed. When a register has not been restored and the next instruction needs it, this instruction gets stalled until the register was restored.

In "dynamic" and "dynamic with no loop" modes, background saving of dirty registers is performed every time an access to the context RAM is possible and allowed by the context switch mode.

### NOTE

The contents of a channel context space in the context RAM depends on the selected context switch mode. In "dynamic" and "dynamic with no loop" modes, the contents of the context RAM tend to match the contents of the SDMA registers (except for the PCU registers and flags that are never saved in the background). In "dynamic power" and "static" modes, the contents of the context RAM remain unchanged until the channel terminates with a done or gets preempted.

#### 41.4.2.4.3 Context Map in Memory

Refer to [Context Switching-Programming](#).

### 41.4.3 Functional Units

The functional units are small systems that are used by the SDMA core to handle data transfers between the core and a bus domain external to the SDMA.

The SDMA core is able to control and exchange data with these systems by sending instructions and reading or writing data from/to the functional units' registers via the FUBUS. This is done with the ldf and stf instructions.

The following sections provide introductions to the available functional units. [Functional Units Programming Model](#) provides descriptions the functional units' behaviors.

#### 41.4.3.1 Burst DMA Unit

The burst DMA unit enables the SDMA core to perform data transfers to and from the ARM platform memory.

It is optimized for accessing SDRAM-like devices. It does not provide control to assign a privilege level to the DMA access. The burst DMA unit provides the SDMA with means to do the following:

- Perform up to 8-beat read and write bursts to the ARM platform memory, which optimizes throughput when accessing SDRAM-type devices because of an internal, 36-byte FIFO
- Access the ARM platform memory at once or twice the SDMA core frequency
- Copy data from one ARM platform memory location to another ARM platform memory location at the ARM platform bus speed, which provides a very high throughput
- Control the method for addressing the ARM platform memory (automatic increment of addresses or frozen addresses-the former aimed at accessing RAM-like memory and the latter aimed at accessing single-address FIFOs)
- Enable or disable automatic prefetch when reading data from the ARM platform memory. When the prefetch mode is selected, the burst DMA automatically triggers external bursts to fill its FIFO without waiting for the SDMA core to request the corresponding data, greatly improving throughput.
- Rely on the DMA to automatically flush its FIFO content when there is enough data to generate an 8-beat burst to the ARM platform memory. Or, it forces a flush when a data transfer must terminate.
- In the former case, the SDMA core may only be stalled when it tries writing data and there is not enough room left in the FIFO. In the latter case, the core is stalled until the data is effectively written to the ARM platform memory.

In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the ARM platform memory. This error status is retrieved by a later access to the burst DMA.

Terminating a write data transfer with a forced flush command guarantees that any bus error to the ARM platform memory is caught.

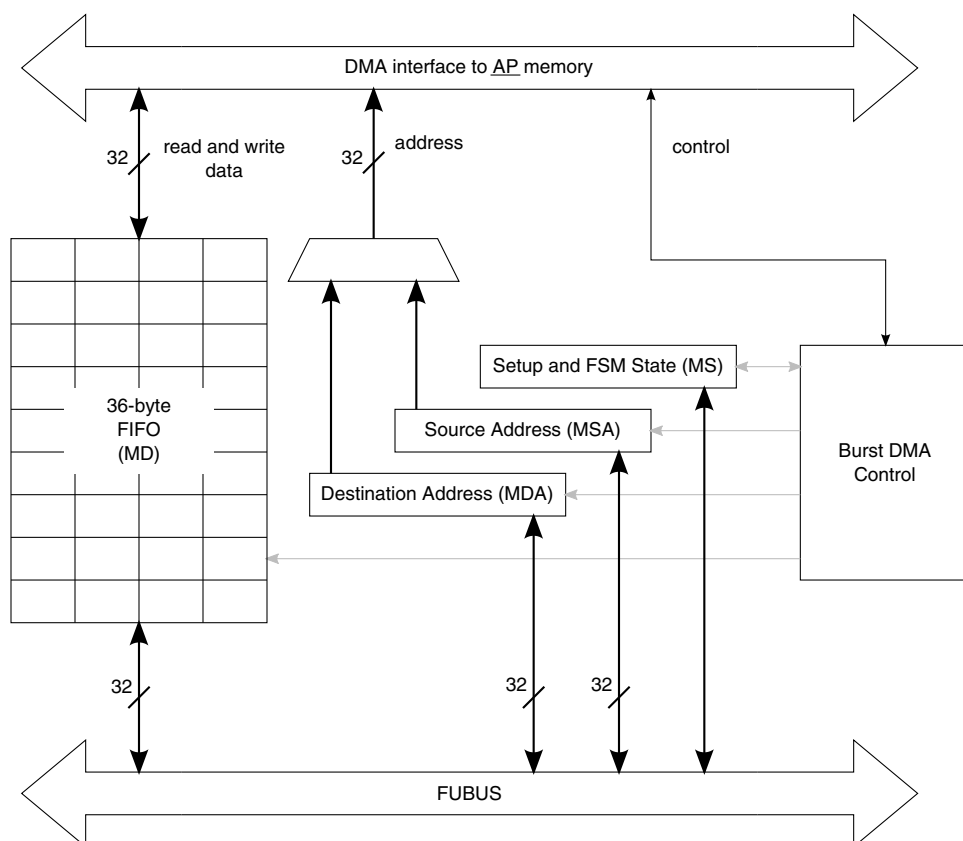

- Handle address alignment issues between the ARM platform memory map and the SDMA core data. This enables the core to read or write 32-bit data from the burst DMA, whereas the corresponding ARM platform address is not 32-bit aligned. This drastically improves the SDMA scripts' efficiency since the same loop that transfers 32 bits at a time can be used regardless of the start and end addresses in the ARM platform memory space.

This unit structure and registers are described in [Burst DMA Structure](#) and [Burst DMA Registers](#).

### 41.4.3.1.1 Burst DMA Structure

The burst DMA is essentially made up of a 36-byte FIFO, address registers, and a controlling state-machine. The 36-byte FIFO enables eight-word buffering with address alignment, and the state-machine manages clock adaptation when required.

The burst DMA is depicted in the figure below.

**Figure 41-9. Burst DMA Structure**

### 41.4.3.1.2 Burst DMA Registers

There are four registers, as follows, that may be accessed from the SDMA core:

- **MSA (Memory Source Address)** - Holds the source byte address in the ARM platform memory map for reading data from this location. This register is automatically modified every time the core reads new data from the FIFO.
- **MDA (Memory Destination Address)** - Holds the destination byte address in the ARM platform memory map for writing data to this location. This register is automatically modified every time the core writes new data into the FIFO.
- **MD (Memory Data)** - Labels the 36-byte FIFO access point: Reading a byte, halfword, or word from MD respectively retrieves the first 1, 2, or 4 bytes of the

FIFO (for example, the bytes that were stored first by the DMA state-machine when transferring data from the ARM platform memory).

- When the FIFO does not hold as many bytes as required by the SDMA core, the core is stalled until the missing bytes are read from the ARM platform memory. In the case of prefetch mode, the DMA controller decides when it should start a burst to ARM platform memory in order to reduce the risk to not have the required data for the future accesses of the core. When there is no prefetching, a burst is triggered when the required data is not available in the FIFO.

Writing a byte, halfword, or word to MD stores 1, 2, or 4 bytes, respectively, at the end of the FIFO (for example, these bytes are transmitted to the ARM platform memory after all the other bytes that were previously stored in the FIFO). When the FIFO does not have enough room left to hold the written data, the SDMA core is stalled until a sufficient amount of FIFO contents are flushed out to the ARM platform memory. Flushing is decided by the DMA controller when there are enough bytes in the FIFO to perform the largest allowed burst to ARM platform memory (the exact size depends on the burst start address and the AHB 1 Kbyte boundary rule). However, the SDMA core has the ability to force the flushing operation at any time, for example, when at the end of the data transfer, prior to channel closure.

- MS (Memory Setup) - Contains the state of the burst DMA control, the two flags that define whether each address register is incremented after every access to the external memory, and another flag that is set when a bus error occurred.

#### 41.4.3.1.3 Burst DMA Data Transfers

Three typical usages have been identified that involve the burst DMA: the data transfer startpoint, the endpoint, or both.

Every case requires a different procedure, as listed in the following sections:

##### 41.4.3.1.3.1 Data Retrieval from the ARM platform Memory

The following steps retrieve data from ARM platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the source address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the source address register itself (MSA).
- Read data from the FIFO using the *ldf MD* instruction as many times as needed. If an error occurred during the fetch from ARM platform memory, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from the FIFO.

#### 41.4.3.1.3.2 Storing Data Into the ARM platform Memory

The following steps store data from ARM platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the destination address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the destination address register itself (MDA).
- Store data into the FIFO using the *stf MD* instruction as many times as needed.
- When the transfer is finished and if the DMA worked in automatic flush mode, force the flush of the FIFO. This instruction is stalled until all the FIFO data is effectively sent to the ARM platform memory and the error status of the transfer is available in the DF flag.

#### 41.4.3.1.3.3 Transferring Data Between Two ARM platform Memory Locations-Burst DMA Unit

The following steps copy data between two ARM platform memory locations using the burst DMA unit:

- Set up the MS flags to reflect the modes for the source and destination addresses (all the combinations are possible), then initialize the source address register (MSA) and the destination address register (MDA). Both addresses must be word-aligned.
- Use as many *stf MD* instructions with the *COPY* flag as needed. Every instruction triggers a burst read of a given number of words from the source address (this number is provided to the burst DMA via the SDMA core general purpose register, which is referenced in the *stf* instruction). Once all the data is loaded into the FIFO, the DMA empties it with a write burst of the same count to the destination address. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the burst DMA to check the error status.

### 41.4.3.2 Peripheral DMA Unit

The peripheral DMA unit is the second functional unit that connects the SDMA to the ARM platform memory.

Unlike the burst DMA, it does not support burst transfers and is optimized for accessing peripherals. It does not provide control to assign a privilege level to the DMA access. Its feature list comprises the following:

- Access to the ARM platform peripherals or memory at once or twice the SDMA core frequency

- Data copy from one ARM platform memory location to another ARM platform memory location at memory bus speed, improving throughput
- Control of the method for addressing the ARM platform memory (automatic increment or decrement of addresses or frozen addresses, the first ones aimed at accessing RAM-like memory and the last one aimed at accessing single-address FIFOs)
- Selectable automatic prefetch when reading data from the ARM platform memory. In prefetch mode, the peripheral DMA automatically fetches another data-without waiting for the SDMA core to request it-when its data register is empty, which improves the throughput
- Selectable automatic flush. In this mode, the SDMA core may only be stalled when it tries writing data and the previous write operation is not finished yet; whereas, in forced flush mode, the core is stalled until the data is effectively written to the ARM platform memory.
- In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the ARM platform memory or the peripheral. This error status is retrieved by a later access to the peripheral DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the ARM platform memory has been caught.

This unit structure and registers are described in [Peripheral DMA Structure](#) and [Peripheral DMA Registers](#).

### 41.4.3.2.1 Peripheral DMA Structure

The peripheral DMA is made up of a 32-bit data register, two address registers, and a controlling state-machine. The state-machine manages clock adaptation, when required.

It is shown in the following figure.

Figure 41-10. Peripheral DMA structure

### 41.4.3.2.2 Peripheral DMA Registers

According to [Figure 41-10](#), the peripheral DMA has four registers that may be read or written by the SDMA core:

- *PD (Peripheral Data)* is the DMA 32-bit data register.
- *PSA (Peripheral Source Address)* holds the source byte address in the ARM platform memory map for reading data from this location. This register is automatically modified every time the core reads a new data from PD.

- *PDA (Peripheral Destination Address)* holds the destination byte address in the ARM platform memory map for writing data to this location. This register is automatically modified every time the core writes a new data into PD.
- *PS (Peripheral Setup)* contains the state of the peripheral DMA control, two configuration fields that define the way address registers are modified after every data access, two additional configuration fields that define the data size to access the source and destination devices, and another field that contains the latest transfer error status.

### **41.4.3.2.3 Peripheral DMA Data Transfers**

There are three typical usages that involve the peripheral DMA, whether it is the data transfer start-point, endpoint, or both.

Every case requires a different procedure, as described in [Data Retrieval from the ARM platform Memory or Peripheral](#), [Storing Data into the ARM platform Memory or Peripheral](#), and [Transferring Data Between Two ARM platform Memory Locations-Peripheral DMA Unit](#).

#### **41.4.3.2.3.1 Data Retrieval from the ARM platform Memory or Peripheral**

The following steps retrieve data from ARM platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the source (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the source address register itself (PSA) with an address that is aligned to the programmed data size.
- Read data from PD using the ldf PD instruction as many times as needed. If an error occurs during the fetch from the ARM platform memory or peripheral, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from PD.

#### **41.4.3.2.3.2 Storing Data into the ARM platform Memory or Peripheral**

The following steps store data to ARM platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the destination (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the destination address register itself (PDA) with an address that is aligned to the programmed data size.

- Store data into PD using the *stf PD* instruction as many times as needed.
- When the transfer is finished and if the peripheral DMA worked in automatic flush mode, force the flush of PD. This instruction is stalled until PD contents are effectively sent to the ARM platform memory or peripheral, and the error status of the transfer is available in the DF flag.

#### 41.4.3.2.3.3 Transferring Data Between Two ARM platform Memory Locations-Peripheral DMA Unit

The following steps copy data between two ARM platform memory locations using the peripheral DMA unit:

- Set up the PS fields to reflect the modes and data size for the source and destination addresses (all the combinations of addressing modes are possible, but both data sizes must be identical), then initialize the source address register (PSA) and the destination address register (PDA). Both addresses must be aligned with the programmed data size.
- Use as many *stf PD* instructions with the *COPY* flag as needed. Every instruction triggers a single read from the source address; a single write of the received data immediately follows. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the peripheral DMA to check the error status.

### 41.4.4 SDMA Security Support

The SDMA provides support to SDMA software to block unauthorized updates to the scripts in RAM.

SDMA supports the following Security modes:

- Open Mode: has full control to load scripts and context into SDMA RAM. This is the default mode.
- Locked Mode: The ARM platform loads scripts and channel contexts at startup when it is still executing known safe software. When finished, it locks the SDMA to prevent further updates to RAM and selected registers. More details described in [Locked Mode](#).

#### 41.4.4.1 Locked Mode

The LOCK bit in the SDMA\_LOCK register provides support for SDMA scripts to freeze RAM contents after the initial bootload routine to prevent future unauthorized updates to SDMA RAM.

After initial RAM contents are uploaded, ARM platform software can set the LOCK bit to secure the RAM contents to prevent future updates by an unauthorized. After the LOCK bit is written with a '1', the SDMA is "locked" until reset.

The LOCK bit can be read in the SDMA's internal memory map in the LOCK register (see Section [SDMA LOCK \(SDMAARM\\_SDMA\\_LOCK\)](#)). SDMA scripts which load information into RAM can check the value of the LOCK bit to determine if an upload to RAM is allowed. If not allowed, the script can refuse to allow the request to copy data into the RAM to continue. The exact use of the LOCK bit in SDMA scripts for security control will be described in SDMA software documentation (see [SDMA Scripts](#)).

While SDMA is locked, attempts to write to the SDMA\_LOCK, CHN0ADR, ILLINSTADDR, and ONCE\_ENB registers will be ignored. All registers remain readable. Writes to other registers are still allowed.

Once the SDMA is locked, the LOCK bit can only be cleared by a reset. A hardware reset will always clear the LOCK bit. A software reset initiated by writing to the RESET register will only clear the LOCK bit if the SRESET\_LOCK\_CLR bit in the SDMA\_LOCK register is set. Since SDMA\_LOCK register cannot be updated if SDMA is locked, the SRESET\_LOCK\_CLR bit must be configured before setting the LOCK bit. The SRESET\_LOCK\_CLR bit will also be cleared by resets that clear the LOCK bit.

The SDMA RISC core uses the ILLINST and CHN0ADDR registers as pointers to determine where to jump to after an illegal instruction or upon boot after a reset. The LOCK bit prevents updates to these registers to protect against unauthorized changes to these pointers.

While SDMA is locked, the ONCE\_ENB register cannot be written to prevent the OnCE under ARM platform control from being used to gain access to SDMA internal memory. If ARM platform control of the OnCE is enabled before setting the LOCK bit, the ARM platform can use the ONCE for debug purpose after LOCK is set.

#### 41.4.5 OnCE and PCU Debug States

The SDMA has two different debug modes in which the OnCE performs debug instructions.

Refer to [Figure 41-4](#) for an example of the PCU states in debug. The following are the two debug states:

- When a channel is running (that is, when CCR and CCPRI are different from 0, which can be read in the PSW register), SDMA can execute a SoftBkpt instruction from the channel script or receive a debug request. When either happens, the SDMA enters its "Classical" *Debug* state, which is described in [OnCE and Real-Time Debug](#).
- When a channel is not running, the SDMA can be in *Sleep* state or in *Sleep after Reset* state. If a debug request is sent to the core, it enters its *Debug in Sleep* state. This debug mode works similarly to the "Classical" *Debug* state, except it returns to the original state (*Sleep* or *Sleep after Reset*) when the debug mode is left via the exec\_core instruction of the OnCE. From this *Debug in Sleep* state, the SDMA can execute a program whereas no channel is running. If a new debug request is sent to the core or if a SoftBkpt is executed, it comes back to this *Debug in Sleep* state.

The OnCE is provided with several instructions that can be executed when the core is in either debug state. The following table summarizes the behavior of these OnCE debug instructions. There exists other secondary OnCE instructions that are described in [OnCE and Real-Time Debug](#).

**Table 41-7. SDMA in Debug Mode**

Instruction	Debug	Debug in Sleep
exec_once	exec_once <instruction>  SDMA executes the <instruction> and returns to the <i>Debug</i> state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.	exec_once <instruction>  SDMA executes the <instruction> and returns to the <i>Debug in Sleep</i> state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.
run_core	run_core <instruction>  SDMA executes the <instruction>, leaves the <i>Debug</i> state and continues executing the channel script from the position where it stopped. This command must not be used with an instruction that modifies the PC value.	run_core <instruction>  SDMA executes the <instruction> and returns to its <i>Sleep</i> or <i>Sleep after Reset</i> initial state. This command must not be used with an instruction that modifies the PC value.
exec_core	exec_core <instruction>  It is similar to run_core except it requires an instruction that changes the PC value (jump, branch...): the SDMA jumps to the new PC value, leaves the <i>Debug</i> state and starts executing instructions from this new PC value.	exec_core <instruction>  If the previous state was <i>Sleep after Reset</i> , the SDMA returns to this state, and Chn0Addr value overrides the PC value.  Otherwise, the SDMA jumps to the new PC value and starts executing instructions from this new PC.

## NOTE

The feature exec\_core in *Debug in Sleep* after *Sleep after Reset* was added for the Channel boot (channel 0) to allow the debugger to return to *Sleep after Reset* state with a new PC

value. The SDMA will be ready to boot at the Chn0Addr address.

#### 41.4.6 SDMA Clocks and Low Power Modes

The SDMA receives several root clocks from the SoC clock controller block and performs adaptive clock gating to optimize its power consumption. From a user standpoint, clock gating and power mode selection are fully automatized inside the SDMA.

Root clock control is available from the SoC clock controller block.

There are numerous clock sources that are used in the SDMA. They belong to one of two possible clock domains listed in the following table, and have frequency constraints within each domain. Clocks are considered asynchronous between domains.

Within the ARM platform/SDMA clock domain, all clocks must come from the same DPLL. The ARM platform DMA interfaces (peripheral DMA and burst DMA) receive their clock from the ARM platform DMA clock source whose frequency can be once or twice the frequency of the SDMA core clock. The DMA interfaces are designed to work at the ARM platform DMA frequency, but the SDMA core is physically limited to a maximum 104 MHz frequency. Since this is lower than the maximum ARM platform DMA frequency, the SDMA core clock is tied to the ARM platform peripheral clock frequency.

The ARM platform Peripheral Bus Clock source must be an exact sub-frequency of the SDMA Core clock source (any integer value greater or equal to 1).

**Table 41-8. Clocking Scheme**

Clock Domain	Source Clock	Comments
ARM platform	SDMA core (SDMA main core)	Source clock for the core and all its operations; this clock is thus used by most of the SDMA sub-blocks.
	ARM platform DMA	DMA interface for the peripheral DMA and the burst DMA. It is balanced with the main clock source, and its frequency is either once or twice the main clock frequency.
	ARM platform peripheral	Connection to the ARM platform peripheral bus. It is a sub-frequency of the main clock frequency.
JTAG	TCK	Clock for JTAG access, limited to maximum of 1/8 of the SDMA core clock frequency.

The JTAG clock is sampled by the SDMA main clock to determine its rising edge. This simplifies design and clock management, but it also adds a ratio constraint between those two clocks. It is guaranteed the JTAG interface works properly when the frequency of TCK is lower than 1/8<sup>th</sup> of the frequency of the SDMA main clock (which is about 8 MHz when the SDMA core clock frequency is 66 MHz).

#### 41.4.6.1 Clock Gating and Low Power Modes

The SDMA automatically performs power saving without requiring user involvement. It implements two levels of automatic clock gating.

##### 41.4.6.1.1 Coarse Clock Gating

Every sub-block clock comes from one of the five available sources, and is gated with the sub-block specific enabling condition.

The following table displays the sub-block clocks and their source. It also indicates the relationships that may exist between different sub-blocks clock enables.

**Table 41-9. Sub-blocks Clocks**

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Core	SDMA Main Core	The core sub-block clock is running when the core is not in one of its sleep states (Sleep or Sleep after Reset) or there is a pending channel. Typically, the core sub-block clock is stopped once all the channels are processed and the core enters its sleep state. A new pending channel awakes the core sub-block clock.	None
Memories	SDMA Main Core	The clock activation only occurs during a core access.	Disabled when Core sub-block clock is disabled or no memory access in progress
Scheduler	SDMA Main Core	Its clock only runs when scheduling is needed: for example, when there are pending channels, upon reception of a DMA request, and anytime the ARM platform modifies the channel running conditions.	None
ARM platform Control	SDMA Main Core & ARM platform peripheral	The ARM platform peripheral clock is solely used to determine the frequency ratio with the SDMA main clock. The control registers' clock is based on <i>SDMA main clock</i> ; it is active when the ARM platform or the SDMA modifies the contents of one of these registers.	None

*Table continues on the next page...*

**Table 41-9. Sub-blocks Clocks (continued)**

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Burst DMA	SDMA Main Core & ARM platform DMA	The burst DMA has two clocks: The first clock is derived from the SDMA main core clock and drives registers that are connected to the FUBUS. The second clock is derived from the ARM platform DMA clock and drives registers that are connected to the ARM platform DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the burst DMA is not used by the running channel script).	Disabled when Core sub-block clock is disabled
Peripheral DMA	SDMA Main Core & ARM platform DMA	The peripheral DMA has two clocks: The first clock is derived from SDMA main clock and drives registers that are connected to the FUBUS. The second clock is derived from the ARM platform DMA clock and drives registers that are connected to the ARM platform DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the peripheral DMA is not used by the running channel script).	Disabled when Core sub-block clock is disabled
OnCE	SDMA Main Core	The OnCE clock is derived from main source clock. It is disabled by default. In order to use the OnCE, its clock must be explicitly turned on, either by enabling the OnCE access from the ARM platform peripheral bus (register ONCE_ENB), or by driving the clk_gating_off input pin high. This is a SDMA input whose driver depends on the SoC implementation (typically a JTAG controller).  The OnCE also receives the TCK input, which is the JTAG clock. It does not use it as a functional clock; the TCK input is sampled instead. Refer to <a href="#">Synchronization Implementation</a> .	When enabled, all other clocks are systematically on (clock gating is off)

#### 41.4.6.1.2 Refined Clock Gating

The SDMA implements a second level of clock gating on a register-per-register basis.

Unlike the first level that covers all the SDMA flip-flops, except the synchronizers (only five flip-flops are always running), the second level is only available for eligible registers, which amounts to about 90% of the SDMA flip-flops.

These gated registers are only clocked when the hardware logic detects a new data loading. This additional gating further reduces dynamic power consumption.

#### 41.4.6.1.3 Low Power Modes and User Control

Power savings are automatically managed by the SDMA hardware without any user involvement; however, one can distinguish three different power modes: SLEEP, RUN, and DEBUG.

The following table describes these modes, and shows how to switch from one mode to another.

**Table 41-10. Power Modes**

Power Mode	Sub-blocks								Comments
	Core	Mem ories	Sch edul er	ARM platf orm Cont rol	CRC	Burs t DMA	Peri pher al DMA	OnC E	
SLEEP	off <sup>1</sup>	off	wait <sup>2</sup>	wait	off	off	off	off	Set when the PCU state is either <i>Sleep</i> or <i>Sleep after Reset</i> and the SDMA is not in DEBUG mode. This is the default mode after reset.
RUN	on <sup>3</sup>	wait	wait	wait	wait	wait	wait	off	Set for the other PCU states that are reachable out of debug: <i>Program</i> , <i>Data</i> , <i>Change of Flow</i> , <i>Error in Loop</i> , <i>Debug</i> , <i>Functional Unit</i> , <i>Save</i> , or <i>Restore</i> .
DEBUG	on	on	on	on	on	on	on	on	Set regardless of the PCU state when clock gating is turned off to use the OnCE features (either <i>clk_gating_off</i> pin high or ONCE_ENB[0] set).

1. *off*: no clock
2. *wait*: only clocked when accessed or stimulated
3. *on*: clock is always running

It is possible to control the SDMA power mode. The procedures to force the SDMA into either mode are described in [SLEEP Mode](#).

#### 41.4.6.1.3.1 SLEEP Mode

This is the default mode after reset; therefore, resetting the SDMA forces this mode.

However, the common procedure is as follows:

- Ensure the *clk\_gating\_off* pin is low and ONCE\_ENB[0] is cleared.
- Disable all channels (via the STOP\_STAT control register, and the HO, DO, EO if necessary).
- Wait for the active channels to complete or force a reschedule via the reschedule bit in the RESET register.
- The SDMA is in SLEEP mode making it possible to completely shut off its clock from the chip level clock controller using the procedure described in [Stop Mode Response](#).

#### 41.4.6.1.3.2 RUN Mode

This is the default mode when a channel is running:

- Ensure the *clk\_gating\_off* pin is low and ONCE\_ENB[0] is cleared.
- Activate at least one channel (via the HSTART control registers, a DMA request, and/or the HO, DO, EO register bits).

#### **41.4.6.1.3.3 DEBUG Mode**

The DEBUG mode must be set when one needs to use the debugging facilities of the SDMA.

- Ensure the SDMA clocks are running from the CCM.
- Set the *clk\_gating\_off* pin high or use the SDMA to set ONCE\_ENB[0].

#### **41.4.6.1.4 Stop Mode Response**

The SDMA receives a stop request from the chip level clock controller. This request may be asserted when the chip enters the stop low power mode.

If the SDMA is running when the request is received, then the SDMA will complete all pending channels before returning to the SLEEP state. The SDMA sends an acknowledgement to the clock controller when the SLEEP state is entered indicating that the SDMA's clocks can be turned off.

### **41.4.6.2 Reset**

After reset (either received from the reset block or a software reset required by the ARM platform), the SDMA is in IDLE mode. It will start its boot code located at address 0 once a channel is activated.

Activating a channel can be done by the ARM platform after programming a positive priority and setting the channel bit in the EVTPEND register.

There will not be a context RESTORE for the first channel (bootload channel) called after a reset because the context data in RAM has not been initialized. Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized. Subsequent calls to the same channel or different channels may use any of the dynamic context modes

## **41.4.7 Software Interface**

Appendix A fully describes the SDMA Application Programming Interface (API).

## 41.4.8 Initialization Information

This section discusses the following:

- [Hardware Reset](#)
- [Channel Script Execution](#)
- [Initialization and Script Execution Setup Sequence](#)

### 41.4.8.1 Hardware Reset

After reset, the program RAM, context RAM, data RAM, and RAM containing the channel enable registers (CHNENBLn) have unpredictable contents.

The active register set is assigned to channel 0 and the PC is initialized to all zeros. However, since the channel enable register is all zeros, there are no active channels and the SDMA is halted waiting for the boot channel to start.

The ARM platform will have to setup the SDMA in order to boot it. The CONFIG register must be initialized to determine the DMA/core clock ratio (1 or 2). Channel Enable Registers must also be initialized.

To start up the SDMA, the ARM platform first creates some channel control blocks (CCB) and buffer descriptors (BD) in ARM platform memory for the boot channel (channel 0) and then initializes the channel 0 pointer register (SDMA\_MC0PTR) to the address of the first control block. [Data Structures for Boot Code and Channel Scripts](#) provides an overview of the data structure for the CCB and BD's. The SDMA\_HSTART, SDMA\_HOSTOVR and SDMA\_EVT OVR registers are then configured according to [Runnable Channels Evaluation](#) to allow channel 0 to run.

Upon being enabled, the SDMA begins executing the script located at the address indicated by the Channel 0 Boot Address register (SDMA\_CHN0ADDR) in the program memory. The reset value of SDMA\_CHN0ADDR points to the default bootloader script in ROM. This ROM script will read the channel 0 pointer register (SDMA\_MC0PTR) to determine the location of the Channel Control Block (SDMA\_CCB) in ARM platform memory. The script will then begin fetching by DMA the first channel control block which contains a pointer to the location channel 0 Buffer Descriptor chain which is also fetched via DMA. If the buffer descriptor contains a valid command, the script interprets the command in each buffer descriptor and proceeds to implement the command and move on to the next buffer descriptor control block. The buffer descriptor commands for

channel zero are typically set up to load SDMA's program RAM, Data RAM, and initial values for the channel contexts. Some channel scripts expect particular parameters to be passed

There are two ways to make the SDMA boot on a user-defined script. The OnCE (either via its JTAG interface or its ARM platform Control interface) can be used to download any code in the SDMA RAM and force the SDMA to boot on that code. Also, the SDMA\_CHN0ADDR register in the ARM platform programming model can be modified to point to user code in RAM which would need to either have been loaded via the ONCE or default bootload routine (ex before a S/W reset).

### **41.4.8.2 Channel Script Execution**

The execution of an SDMA script depends on both the instructions that make up the script, the data context upon which it operates, and commands or parameters allowed to the buffer. All these items must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate context, but may share scripts and locations in data RAM.

Channels are initialized by the ARM platform by using channel 0 to download any required scripts and data values and the channels initial context. The context contains all the initial values of the SDMA core registers. This includes the Program Counter (PC) which is set to the start of the desired script in SDMA program memory.

The ARM platform selects which trigger conditions that must occur for the channel to start by configuring the SDMA\_CHNENBL, SDMA\_HOSTOVR and SDMA\_EVT OVR registers. The trigger events include ARM platform setting HE (SDMA\_HSTART) or a hardware DMA request asserts an event input to SDMA. The channel can become active according to its priority compared with other runnable channels when the selected trigger(s) cause the condition described in [Runnable Channels Evaluation](#) to evaluate as true.

The specific parameters to be passed to each script in the buffer descriptor or context are documented in the software documentation for each script. Please refer to [SDMA Scripts](#) for complete script documentation. [Buffer Descriptor Format](#) provides an overview of the buffer descriptor format.

### **41.4.8.3 Initialization and Script Execution Setup Sequence**

To summarize, the following steps are minimally required to setup SDMA and run channel scripts.

- Perform Hardware Reset. The program RAM, context RAM, data RAM and SDMA\_CHNENBLn registers have unpredictable contents after this reset.
- Initialize SDMA\_CHNENBLn registers to map DMA request events to desired channels.
- Configure SDMA\_CHNPRIn registers to select priority for runnable channels. A non-zero priority is required for the channel to run.
- Configure the SDMA\_CONFIG register to select DMA to SDMA core clock ratio .
- Set up channel control blocks and buffer descriptors in ARM platform to specify the loading of SDMA program RAM and channel contexts for each SDMA channel to be used. Reference [Data Structures for Boot Code and Channel Scripts](#).
- Configure SDMA\_MC0PTR register with base address of ARM platform Channel Control Block base address.
- Initialize SDMA\_CHNENBLn registers to map DMA request events to associated channel. Reference [Mapping DMA Requests to Pending Channels](#).
- Configure SDMA\_CHNPRIn registers to set priority for each channel to be run.
- For each channel to be run, configure SDMA\_HOSTOVR (HO) and SDMA\_EVT OVR (EO) registers to select which events (hardware and/or software trigger events) must occur for the channel to be runnable. Reference [Runnable Channels Evaluation](#).
- Set bit 0 of the SDMA\_HSTART register to set HE[0] and allow Channel 0 to run (assumes EO[0] and DO[0] were both set in previous step). This will cause SDMA to load the program RAM and channel contexts configured previously.
- Wait for Channel 0 to finish running. This is indicated by HI[0]=1 in the SDMA\_SDMA\_INTR register, or by optional interrupt to the ARM platform.
- Set the LOCK bit in the SDMA\_SDMA\_LOCK register to prevent un-authorized uploads of data to SDMA RAM.
- Additional channel scripts can now be run by enabling the selected software or hardware trigger event according to [Runnable Channels Evaluation](#).

### 41.4.9 SDMA Programming Model

This section describes the programming model for the SDMA RISC engine, including its processor, memory, and internal control registers.

All addresses are related to the internal SDMA memory map, which is completely different from the ARM platform memory maps. The ARM platform processor has no access to any hardware resource described, except when those resources are described in ARM Platform Memory Map and Control Register Summary. .

### 41.4.9.1 State and Registers Per Channel

The SDMA can be seen as a set of 32 identical devices that are able to perform one data transfer channel each. Only one channel can work at a time, but every channel state is available at any time.

This chapter lists the components of every channel state.

### 41.4.9.2 General Purpose Registers

Each channel has eight general purpose registers of 32 bits for use by scripts. General register 0 has a dedicated function for the loop instruction, but otherwise can be used for any purpose.

### 41.4.9.3 Functional Unit State

Each channel context has some state that is part of the functional units.

The specific allocation of this state is part of the functional unit definition that is described in [Burst DMA Unit Programming](#), [Peripheral DMA Unit Programming](#).

This state must be saved/restored on context switches.

#### 41.4.9.3.1 Program Counter Register (PC)

The PC is 14 bits. Since instructions are 16 bits in width and all memory in the SDMA is 32 bits in width, the low order bit of the PC selects which half of the 32-bit word contains the current instruction.

A low order bit of zero selects the most significant half of the word.<sup>1</sup>

#### 41.4.9.3.2 Flags

Each channel has the following four flags:

- The T bit reflects the status of some arithmetic and test instructions. It is set when the result of an addition or a subtraction is zero and cleared otherwise. It is also the copy of the tested bits. Finally, it can also be set when the loop counter (GReg0) reaches zero. When the last instruction of the hardware loop is an operation that can modify the T flag, its effect on T is discarded and replaced by the GReg0 status.

---

1. For example, big-Endian.

- Two additional bits, SF and DF, are used to indicate error conditions resulting from loading data sources and storing to destinations, respectively. Access errors set these bits, and successful transactions clear them. They can also be cleared by specific instructions (CLRF and loop). The source fault (SF) is updated by the loads LD and LDF; the destination fault (DF) is updated by the stores ST and STF.
- Access errors are caused by several conditions including writing to the ROM, writing to a read-only memory mapped register, accessing an unmapped address, or any transfer error received by a peripheral when it is accessed.

The SF and DF flags have a major impact on the behavior of the hardware loop: If SF or DF is set when starting a hardware loop and it is not masked by the loop instruction, the loop body will not be executed. Inside the loop body, if a load or store sets the corresponding SF or DF flag, the loop exits immediately. Testing the status of the T flag at the end of the loop (as well as testing both SF and DF) tells if the loop exited abnormally as any anticipated exit prevents GReg0 from reaching the zero value and thus setting the T flag. This is also valid if the fault occurs at the last instruction of the last loop.

- The last flag is the loop mode flag, LM, which is composed of two bits. The most significant bit indicates when the processor is currently operating in loop mode. It is set by the loop instruction and is cleared after execution of the last instruction of the last loop. The least significant bit is set when the program counter points to the last instruction of a loop on the last path. It is used for a channel that is restored with this configuration to know that the next program counter is EPC. As with the dynamic context switch GReg0, which indicates when the program must get out of the loop, it can be restored only on the last instruction of the loop. This, however, is too late to fetch the next instruction after the loop.

#### 41.4.9.3.3 Return Program Counter (RPC)

The RPC is 14 bits. It is set by the jump to the subroutine instructions and used by the return from the subroutine instructions.

Instructions are available to transfer its contents to and from a general register.

#### 41.4.9.3.4 Loop Mode Start Program Counter (SPC)

The SPC is 14 bits. It is set by the loop instruction to the location immediately following it.

### 41.4.9.3.5 Loop Mode End Program Counter (EPC)

The EPC is 14 bits. It is set by the loop instruction to the location of the next instruction after the loop.

### 41.4.9.4 Context Switching-Programming

Each channel has a separate context consisting of the eight general purpose registers and additional registers representing the state of the functional units.

The active registers and functional units contain the context of the active channel. The context of inactive channels is stored in SDMA RAM, which is part of the SDMA address space.

In a function of the selected context switching mode ([Context Switching](#)), modified registers by the program can be saved in the channel RAM space while the program is going on. In every cycle, a write access to the RAM is possible.

On a done or yield(ge) instruction, SDMA goes into "real" context switching. In one of the dynamic modes, modified registers not previously saved, as well as the PC-Loop registers, are stored into the context area of the channel that will be closed. The new PC-Loop registers are loaded from the context area of the new channel. All other registers are restored while the program is executed, giving priority to registers used by the decoded instruction. Therefore, in the best case, only the PC and Loop registers should be saved and restored during this context-switching phase, which only requires five SDMA cycles.

In static mode, the context switch stores all registers in the old channel RAM space, and restores all registers from the new channel RAM space. It requires 26 SDMA cycles.

The address of the context memory for channel  $i$  is  $CONTEXT\_BASE + 24*i$  or  $CONTEXT\_BASE + 32*i$  where  $CONTEXT\_BASE$  equals 0x0800. The table below presents the layout of a channel context in memory:

**Table 41-11. Layout of a Channel Context in Memory for SDMA**

#### 41.4.9.5 Address Space

The SDMA has four internal buses which are listed here.

- The Instruction bus reads instructions from the memory. Its address map is described in [Instruction Memory Map](#).
- The Data bus (DMBUS) accesses the same memories as those visible on the Instruction bus, some memory-mapped registers (scheduler status and OnCE registers), and up to 14 peripherals. Its address map is described in [Data Memory Map](#).

- The Functional Units bus (FUBUS) accesses the , Burst DMA, Peripheral DMA . The addressing mechanism is further detailed in [Functional Units Programming Model](#).
- The Context Switch bus reads/writes registers into context-switch RAM space. It is a 64-bit bus dedicated for accessing this RAM space for updating the context of the running channel. While the program is going on, this bus has the lowest priority compared to the Instruction and Data buses, except for restoring a register needed for the decoded instruction to be executed. On the save part of a context switch (when the PCU is in its slave state), this is the only one used. On the restore part, the Instruction bus has the priority to read the next instruction at the restored PC and otherwise the Context Switch bus is used. It is not possible to control the actual data transfers that occur on this bus.

#### 41.4.9.5.1 Instruction Memory Map

The instruction memory map is based on a 14-bit address bus and a 16-bit data (instruction) bus. Each address corresponds to a 16-bit data location.

Instructions are fetched from either program ROM or program RAM. An SDMA script is able to change the contents of the program RAM, which is also visible from the data bus.

The first two instruction locations (at 0 and 1) are special. Location 0 is where the PC is set on reset. Location 1 is where the PC is set upon the execution of an illegal instruction. It is expected that both of these locations will contain a jmp to handle routines.

**Table 41-12. SDMA Instruction Memory Space**

Device	SDMA Address (Hex)	Base Address Label	Block Name	WS	Description
ROM	0x0000 ↓ 0x07FF	SDMA_IBUS_ROM_ADDR	-	0	4 Kbyte internal ROM with boot code and standard routines.
RAM	0x1000 ↓ 0x1FFF	SDMA_IBUS_RAM_ADDR	-	0	8 Kbyte internal RAM with channels context and user data/routines.

#### 41.4.9.5.2 Data Memory Map

All of the data accessible to SDMA scripts make up the data memory space of the SDMA.

This address space has several components:

- ROM (also visible on the Instruction bus)
- RAM (also visible on the Instruction bus)

- Shared Peripherals Registers
- SDMA Internal Registers (scheduler, OnCE, and registers that are also accessible by the ARM platform)

SDMA scripts can read and write to the context RAM, data RAM, shared peripheral registers, and internal registers.

The address range is 16 bits and the data width is 32 bits. Each address corresponds to a 32-bit data word. When accessing peripheral registers (USB and so on), the data width may be different. The exact address map for the peripherals depends on the project (as presented in each respective chapter).

Data access is performed with *ld* and *st* instructions that take the address from a general purpose register in the core (GRegn). The mapping between the general purpose register contents and the address bus is given in the following table:

**Table 41-13. GRegn to DMBUS Address Mapping**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sz	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
address															

Grayed bits are simply discarded but they must be cleared to ensure forward-script compatibility.

- sz (bit 31) indicates the peripheral data width: 0 is used for a 32-bit peripheral and 1 is used for a 16-bit peripheral.
- address (bits 15 down to 0) is the address of the accessed resource (internal memory, internal register, or shared peripheral).

**Table 41-14. SDMA Data Memory Space**

Device	SDMA Address (Hex)	Size	Description
ROM	0x0000 → 0x03FF	4 Kbyte	4 Kbyte internal ROM with boot code and standard routines
Reserved	0x0400 → 0x07FF	4 Kbyte	4 Kbyte Reserved
RAM	0x0800 → 0x0FFF	8 Kbyte	8 Kbyte internal RAM with channels contexts and user data/routines
per1	0x1000 → 0x1FFF	16 Kbyte	<i>peripheral 1</i> memory space (4 Kbyte peripheral's address space)
per2	0x2000 → 0x2FFF	16 Kbyte	<i>peripheral 2</i> memory space (4 Kbyte peripheral's address space)
per3	0x3000 → 0x3FFF	16 Kbyte	<i>peripheral 3</i> memory space (4 Kbyte peripheral's address space)
per4	0x4000 → 0x4FFF	16 Kbyte	<i>peripheral 4</i> memory space (4 Kbyte peripheral's address space)
per5	0x5000 → 0x5FFF	16 Kbyte	<i>peripheral 5</i> memory space (4 Kbyte peripheral's address space)
per6	0x6000 → 0x6FFF	16 Kbyte	<i>peripheral 6</i> memory space (4 Kbyte peripheral's address space)
Registers	0x7000 → 0x7FFF	16 Kbyte	Memory mapped registers

*Table continues on the next page...*

**Table 41-14. SDMA Data Memory Space (continued)**

Device	SDMA Address (Hex)	Size	Description
per7	0x8000 → 0x8FFF	16 Kbyte	<i>peripheral 7</i> memory space (4 Kbyte peripheral's address space)
per8	0x9000 → 0x9FFF	16 Kbyte	<i>peripheral 8</i> memory space (4 Kbyte peripheral's address space)
per9	0xA000 → 0xAFFF	16 Kbyte	<i>peripheral 9</i> memory space (4 Kbyte peripheral's address space)
per10	0xB000 → 0xBFFF	16 Kbyte	<i>peripheral 10</i> memory space (4 Kbyte peripheral's address space)
per11	0xC000 → 0xCFFF	16 Kbyte	<i>peripheral 11</i> memory space (4 Kbyte peripheral's address space)
per12	0xD000 → 0xDFFF	16 Kbyte	<i>peripheral 12</i> memory space (4 Kbyte peripheral's address space)
per13	0xE000 → 0xEFFF	16 Kbyte	<i>peripheral 13</i> memory space (4 Kbyte peripheral's address space)
per14	0xF000 → 0xFFFF	16 Kbyte	<i>peripheral 14</i> memory space (4 Kbyte peripheral's address space)

## 41.4.10 SDMA Initialization

Appendix A describes the setup of the SDMA . This section provides a quick description of several initialization procedures.

### NOTE

There may be differences with the actual implementation in the API.

### 41.4.10.1 Hardware Reset-SDMA

After reset, the RAM that holds contexts, data, scripts, and the DMA request-channels matrix has unpredictable content.

The core registers are all reset to 0, including the PC; the PCU state is *Sleep after Reset*. No channel can be activated because all of the priorities are also reset to 0.

### 41.4.10.2 Standard Boot Sequence

The following is the standard boot sequence:

1. Initialize the CONFIG register-detailed in [Configuration Register \(SDMAARM\\_CONFIG\)](#)-to determine the ARM platform DMA/core clock ratio (1 or 2)
2. Initialize the DMA request-channels matrix (see [Channel Enable RAM \(SDMAARM\\_CHNENBL<sub>n</sub>\)](#) ).
3. Program the channel control registers-[Channel Event Override \(SDMAARM\\_EVTOVR\)](#), [Channel BP Override \(SDMAARM\\_DSPOVR\)](#), [Channel](#)

BP Override (SDMA\_HOSTOVR), and [Channel Event Pending \(SDMAARM\\_EVTPEND\)](#)-according to the channel allocation.

4. Perform any necessary setup as required by the standard boot script in ROM (this is described in Appendix A).
5. Trigger channel 0 with the [Channel Start \(SDMAARM\\_HSTART\)](#) register, which starts the execution of the ROM script starting at address 0. This boot downloads channel scripts and contexts in RAM.

### 41.4.10.3 User-Defined Boot Sequence

The following is a user-defined boot sequence:

1. Initialize the [Configuration Register \(SDMAARM\\_CONFIG\)](#)[Channel Enable RAM \(SDMAARM\\_CHNENBL \$n\$ \)](#), [Channel Event Override \(SDMAARM\\_EVTOVR\)](#), [Channel BP Override \(SDMAARM\\_DSPOVR\)](#), [Channel ARM platform Override \(SDMAARM\\_HOSTOVR\)](#), and [Channel Event Pending \(SDMAARM\\_EVTPEND\)](#).
2. Use the OnCE (either via its JTAG interface or its ARM platform control registers) to download any code in the SDMA RAM. [Accessing the Memory](#) describes how to write data to the RAM via the OnCE.
3. Use the OnCE instructions to make the PC default value point to the new boot script start address, or rely on the ROM startup script, which first jumps to the address in [Channel 0 Boot Address \(SDMAARM\\_CHN0ADDR\)](#). (This register default address points to the standard boot script.)

### 41.4.10.4 Script Loading and Context Initialization

The execution of an SDMA script depends on both the instructions that make up the script and the data context upon which it operates. Both must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate data context, but may share scripts and locations in the data RAM.

The ARM platform manages the space in program RAM and data RAM. It also manages the assignment of SDMA channels to the device drivers that need them. Channels are initialized by the ARM platform via the channel 0 boot script. The boot channel downloads any required scripts with their data and the channels' initial contexts. Every context contains all the initial values of the registers, including the PC. Then the ARM platform can enable any channel that becomes active and begins fetching and executing instructions from its script.

## 41.4.11 Instruction Description

The following sections introduce the instruction of the SDMA.

Instruction set details are available in [Instruction Set](#).

### 41.4.11.1 Scheduling Instructions

The following are scheduling instructions:

- **done**-The instruction causes certain scheduling or interrupt bits to be set or cleared, which may cause a change in the schedule-ability of the running channel. Then the instruction causes the SDMA to evaluate the current scheduling priorities and to choose the highest priority ready channel. If this channel is not the current channel, a context switch will take place. If there are no runnable channels, the SDMA will enter the stopped mode. The done 5 has a special usage reserved for debug, as explained in [Debug Instructions](#).
- **yield**-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater than the current channel priority.
- **yieldge**-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater or equal to the current channel priority.
- **notify**-The notify instruction affects the scheduling bits, but does not cause rescheduling.

### 41.4.11.2 Conditional Branch Instructions

The conditional branch instructions of an 8-bit displacement, which is sign-extended and added to the current PC (which points to the next instruction) if the condition is satisfied.

Otherwise, control passes to the next sequential instruction.

- **BF**-Branch if False. The branch is taken if the T bit in the processor status is zero (false).
- **BT**-Branch if True. The branch is taken if the T bit in the processor status is one (true).

- **BSF-Branch if Source Fault.** The branch is taken if the SF bit in the processor status is one.
- **BDF-Branch if Destination Fault.** The branch is taken if the DF bit in the processor status is one.

### 41.4.11.3 Unconditional Jump Instructions

There are two varieties of unconditional control transfers: an absolute transfer and a through-register transfer.

Absolute transfers have a 14-bit address field that replaces the current PC.

- **JMP-Jump.** Causes the processor to jump to an absolute address encoded in the instruction itself.
- **JSR-Jump to Subroutine.** Causes the processor to jump to a subroutine, the address of which is encoded in the instruction itself.
- **JMPR-Jump through Register.** Causes the processor to jump to an absolute address contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.
- **JSRR-Jump to Subroutine through Register.** Causes the processor to jump to a subroutine, the address of which is contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.

### 41.4.11.4 Subroutine Return Instructions

The following are subroutine return instructions:

- **RET-Return from Subroutine.** The RET restores the contents of RPC to PC.
- **LDRPC-Load from RPC to Register.** The LDRPC instruction is meant to be used when more than one level of subroutines are required. It stores the contents of RPC in any General register.

### 41.4.11.5 Loop Instruction

The following is a loop instruction:

**LOOP-Enters Loop Mode.** Before entering loop mode, the loop instruction can optionally clear the fault flags (SF and/or DF) based on a 2-bit field in the instruction. This feature is linked to the fact that setting SF or DF in loop mode will cause an immediate exit of the loop.

### 41.4.11.6 Miscellaneous Instructions

The following are miscellaneous instructions:

- **CLRF**-Clear Fault Flags. This instruction clears any combination of SF and DF.
- **MOV r,s**-This moves data from GReg[s] to GReg[r].
- **LDI r,immediate**-This loads GReg[r] with a zero-extended immediate value.

### 41.4.11.7 Logic Instructions

The following are logic instructions:

- **XORr,s**-This performs an exclusive or between GReg[r] and GReg[s], and stores the result in GReg[r].
- **XORIr,immediate**-This performs an exclusive or between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- **ORr,s**-This performs an or between GReg[r] and GReg[s], and stores the result in GReg[r].
- **ORIr,immediate**-This performs an or between GReg[r] and a zero-extended immediate value and, stores the result in GReg[r].
- **ANDNr,s**-This performs an and between GReg[r] and the negated GReg[s], and stores the result in GReg[r].
- **ANDNIr,immediate**-This performs an and between GReg[r] and the negated zero-extended immediate value, and stores the result in GReg[r].
- **ANDr,s**-This performs an and between GReg[r] and GReg[s], and stores the result in GReg[r].
- **ANDIr,immediate**-This performs an and between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

### 41.4.11.8 Arithmetic Instructions

Arithmetic instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the result is zero, otherwise it is cleared.

- **ADD r,s**-This performs the addition of GReg[r] and GReg[s], and stores the result in GReg[r].
- **ADDI r,immediate**-This performs the addition of GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

- **SUB r,s**-This performs the subtraction of GReg[s] from GReg[r], and stores the result in GReg[r].
- **SUBIr,immediate**-This performs the subtraction of a zero-extended immediate value from GReg[r], and stores the result in GReg[r].

#### 41.4.11.9 Compare Instructions

Compare instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the comparison is true, otherwise it is cleared.

##### NOTE

Only one version of the immediate form is implemented. Non-equality comparisons to immediate values will require two instructions.

- **CMPEQ r,s**-This sets T when registers GReg[r] and GReg[s] are equal.
- **CMPEQIr,immediate**-This sets T when register GReg[r] and the zero-extended immediate value are equal.
- **CMPLTr,s**-This sets T when register GReg[r] is less than and not equal to GReg[s]. The comparison is signed.
- **CMPHS r,s**-This sets T when register GReg[r] is greater than or equal to GReg[s]. The comparison is signed.

#### 41.4.11.10 Test Instructions

Test instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if any bit in the result is one, otherwise it is cleared.

- **TSTr,s**-This performs an and between GReg[r] and GReg[s], and sets T if the result is not zero.
- **TSTIr,immediate**-This performs an and between GReg[r] and a zero-extended immediate value, and sets T if the result is not zero.

#### 41.4.11.11 Byte Permutation Instructions

These instructions shuffle the bytes in a register. For the purpose of describing these instructions, have the bytes in a register be numbered from the most significant as  $b_3$ ,  $b_2$ ,  $b_1$ ,  $b_0$ .

- **RORBr**-The rotate right byte. The result is  $b_0$ ,  $b_3$ ,  $b_2$ ,  $b_1$ .

- REVB<sub>r</sub>-The reverse bytes in word. The result is  $b_0, b_1, b_2, b_3$ .
- REVBLO<sub>r</sub>-The reverse, two low-order bytes. The result is  $b_3, b_2, b_0, b_1$ .

#### **41.4.11.12 Bit Shift Instructions**

The following are bit shift instructions:

- ROR1<sub>r</sub>-The rotate right 1 bit. This instruction does a circular right shift of 1 bit.
- LSR1<sub>r</sub>-The logical shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by a 0.
- ASR1<sub>r</sub>-The arithmetic shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by itself.
- LSL1<sub>r</sub>-The logical shift left 1 bit. This instruction shifts all bits to the left by 1. The low order bit is replaced by zero.

#### **41.4.11.13 Bit Manipulation Instructions**

- BCLR<sub>r,n</sub>-The bit clear is immediate; clears bit number  $i$  in register  $r$ .
- BSET<sub>r,n</sub>-The bit set is immediate; sets bit number  $i$  in register  $r$ .
- BTST<sub>r,n</sub>-The bit test is immediate; tests bit number  $i$  in register  $r$  (T becomes equal to the selected register bit).

#### **41.4.11.14 SDMA Memory Access Instructions**

All memory accesses are 32 bits.

Any memory location that is implemented with less than 32 bits (for example, peripheral registers) causes unimplemented bits to be read as 0s.

All memory accesses will cause either the SF or DF flags in the processor status to be set if they cause a fault.

What constitutes a fault, especially when accessing peripheral registers, is a property of the memory location.

- LDr,(b,d)-The load instruction creates an address by adding the displacement field (d) to the contents of the base register (b). The SDMA location at the resulting address is read and placed in the destination register (r).
- ST<sub>r</sub>,(b,d)-The store instruction creates an address in the same manner as the load instruction. The register (r) is stored in the SDMA location at the resulting address.

### 41.4.11.15 Functional Unit Instructions

The functional unit instructions have an 8-bit field that is placed on the functional unit bus.

Some of these bits are used to select which functional unit should be involved in the transfer. The remaining bits are decoded by the selected functional unit so their specific use depends on the functional unit. See [Functional Units Programming Model](#).

There are two functional unit instructions, as follows:

- LDFr,fub-The 8-bit field is placed on the functional unit bus and a read is issued to the selected functional unit. As a result of this instruction, the SF may be set in the processor status.
- STFr,fub-The 8-bit field is placed on the functional unit bus and a write is issued to the selected functional unit. As a result of this instruction, the DF may be set in the processor status.

### 41.4.11.16 Illegal Instructions

All instruction encodings that are illegal cause the following actions:

- The current PC (which points to one beyond the offending instruction) is put in the EPC register.
- The loop mode bit is cleared.
- The PC is set to the value stored in the [Illegal Instruction Trap Address \(SDMAARM\\_ILLINSTADDR\)](#) register (the default value is 0x0001).

ILLEGAL-Although any instruction other than those indicated in the SDMA specification will trigger the illegal instruction mechanism, the ILLEGAL instruction code is preferred as it will always be kept as *illegal* in the possible future versions of the SDMA core.

### 41.4.11.17 Debug Instructions

The following are debug instructions:

- SOFTBKPT-The software breakpoint instruction causes the core to stop and enter debug mode. The core can then be accessed and started by the OnCE debug block only.

- done 5-This instruction is used for debugging, as it copies the contents of the PCU registers and flags to the context memory. Information on this instruction is described in [Saving the Context](#).
- CpShReg-This instruction copies the context memory into the PCU registers and flags. Modifying the corresponding memory location before executing this instruction enables you to have the channel continue from a new instruction address. This instruction is described in [Restoring the Context](#).

## 41.4.12 Functional Units Programming Model

The functional unit instructions cause an 8-bit code, found in the low eight bits of the instruction, to be asserted on the functional unit control bus.

Some of these bits are used to select one of several functional units. Functional units which can be selected include SDMA registers such as MSA and MSD which are not mapped in the SDMA memory map, and are accessible only through the functional unit bus. These Functional Unit Registers are listed in the following table. In order to establish a programming convention, assume the selection bits are some number of the most significant bits of the 8-bit code. Furthermore, some number of the least significant bits is decoded by a given functional unit to establish the type of operation to perform.

**Table 41-15. Functional Unit Registers**

Functional Unit	Register	Register Name	Section/Page
<a href="#">Burst DMA Unit Programming</a>	SDMSA	Memory Source Address Register	<a href="#">Memory Source Address Register (MSA)</a>
	MDA	Memory Destination Address Register	<a href="#">Memory Destination Address Register (MDA)</a>
	MD	Memory Data Buffer Register	<a href="#">Memory Data Buffer Register (MD)</a>  (Write) <a href="#">Burst DMA Write (stf)</a>  (Read) <a href="#">Burst DMA Read (ldf)</a>
	MS	Memory State Register	<a href="#">State Register (MS)</a>

*Table continues on the next page...*

**Table 41-15. Functional Unit Registers (continued)**

Functional Unit	Register	Register Name	Section/Page
Peripheral DMA Unit Programming	PSA	Peripheral Source Address Register	Peripheral Source Address Register (PSA)
	PDA	Peripheral Destination Address Register	Peripheral Destination Address Register (PDA)
	PD	Peripheral Data Buffer Register	Peripheral Data Register (PD)  (Write) Peripheral DMA Write (stf)-Write Mode  (Read) Peripheral DMA Read (ldf)-Read Mode
	PS	Peripheral State Register	Peripheral State Register (PS)

More information regarding the functional units can be found in [Peripheral DMA Unit](#), and [Burst DMA Unit](#).

#### 41.4.12.1 Burst DMA Unit Programming

The DMA instructions control the DMA state machine and may cause a DMA cycle on the associated memory bus.

There are four registers associated with the burst DMA unit: a Memory Source Address register (MSA), a Memory Destination Address register (MDA), a Memory Data buffer (MD), and a state register (MS). The burst DMA has two different uses:

- A data transfer between External Memory Interface and SDMA general register
- A data transfer in copy mode where blocks of data are transferred from the source address to the destination address

##### 41.4.12.1.1 Memory Source Address Register (MSA)

The source address register contains the pointer into EXTMC memory associated with the next read data transfer. It has byte granularity.

Reading the register with the ldf instruction has no side effects, and gives the address value in the EXTMC memory of the next data that is read by the SDMA during an ldf MD instruction.

Writing the source address register has two side effects: If the prefetch bit is set, a DMA read cycle (8-word read access) is issued with the new address. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MSA to guarantee all the data is effectively written to memory.

The MSA register has two modes of programming:

- Frozen-In frozen mode, the MSA register is not modified after DMA accesses.
- Incremented (default mode)-In incremental mode, MSA is incremented by the number of bytes transferred during read cycles.

#### **41.4.12.1.2 Memory Destination Address Register (MDA)**

The destination address register contains the pointer into EXTMC memory associated with the next write data transfer. It has byte granularity.

Reading the MDA register with the ldf instruction has no side effects. It gives the address value in the EXTMC memory where the next SDMA data (stf r,MD instruction) is stored when MD FIFO is flushed.

Writing the destination address register has one side effect. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MDA to guarantee all the data is effectively written to memory.

The MDA register has two modes of programming:

- Frozen-In frozen mode, the MDA register is not modified after DMA accesses.
- Incremented (default mode)-The MDA register is incremented by the number of bytes transferred during write cycles.

#### **41.4.12.1.3 Memory Data Buffer Register (MD)**

The data buffer register consists of a bank of 36 bytes that behave like FIFO.

This FIFO stores the eight words received when a read burst is triggered by the DMA (DMA is in read mode).

The MD register is in write mode after a writing in MDA or after an stf MD instruction.

In that case, a burst write access is automatically triggered when there are more than eight words in MD. For bandwidth optimization, any transfers between DMA and the EXTMC controller are based on burst accesses.

An `ldf r,MD|SIZE` instruction that reads the data buffer may cause a DMA cycle, as follows:

- If there are less bytes in the FIFO than the size parameter of the instruction. For instance, if only two bytes are available in MD and a 4-byte read is requested, a burst read access is executed to complete the two bytes.
- If the prefetch bit is set, and after reading there is enough space in the FIFO to store a full burst, a burst read access is triggered.

An `stf r,MD|SIZE` instruction that writes to the data buffer may cause a DMA cycle if the number of written bytes in MD is higher than 32 (eight words) or if the flush bit is set.

When DMA is used for data transfer between SDMA and EXTMC (reading or writing), no immediate error is possible because the block manages a data misalignment issue; therefore, it is allowed to read/write a word to/from a half-word address. However, the addresses (source or destination) must belong to the EXTMC memory mapping. The only potential error, in this mode, would be the error sent back by the EXTMC controller when an access to a super-user page is detected. The whole transfer on the DMA associated bus will be considered successful when there are no errors seen on the bus during the transfer. In copy mode, an immediate error could be returned to SDMA as described in [Burst DMA Unit Error Management](#).

#### 41.4.12.1.4 State Register (MS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer. MS is also accessed to set-up the conditional yielding feature.

The initialization value of this register is 0 and it consists of the following:

**Table 41-16. SDMA\_MS Structure**

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	spriv	stype	0	0	dpriv	dtype
W																
R	0	0	0	0	y	d	e		0	0	n					
W																

**Table 41-17. SDMA\_MS Field Descriptions**

Field	Description
31-22	Reserved

*Table continues on the next page...*

**Table 41-17. SDMA\_MS Field Descriptions  
(continued)**

Field	Description
21 spriv	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
20 stype	Source Mode. Indicates if MSA has to be incremented (or not) during accesses. 0 Frozen-MSA is not modified. 1 Incremented-MSA is incremented by the number of transferred bytes during read access.
19-18	Reserved
17 dpriv	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved
16 dtype	Destination Mode. Indicates if MDA has to be incremented (or not) during accesses. 0 Frozen-MDA is not modified. 1 Incremented-MDA is incremented by the number of transferred bytes during write access.
15-12	Reserved
11 y	Conditional Yielding selector. When selected, theyield/yieldge instructions will not switch channels if the Burst DMA is in Write Mode, and it has less than four bytes in its FIFO. This is aimed at reducing the number of inefficient FIFO flushes due to context switches. 0 Always yields 1 Yields conditionally (when there are less than four bytes in the FIFO in write mode)
10 d	Access Direction or DMA Mode. DMA is in write mode when data was written into MD by stf MD instructions, or if a previous DMA cycle on the external bus was a write access. Writing MDA or MSA changes the DMA mode to the respective value. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by SDMA with an ldf MD instruction. Reading MDA or MSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 <i>reserved</i> 10 Error mode 11 error read burst
7-6	Reserved
5-0 n	Number of bytes in the MD FIFO.

#### 41.4.12.1.5 Burst DMA Write (stf)

When received from a stf instruction, the function code bits are interpreted as follows, depending on the addressed register:

**Table 41-18. STF Code Bits**

Register	7	6	5	4	3	2	1	0
MSA	s		p	freeze	r			spriv
MDA								dpriv
MD			f	cpy			sz	
MS								

**Table 41-19. STF Code Bit Field Descriptions**

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MSA)	Prefetch Flag 0 No prefetch 1 Prefetch required from new MSA
5 f (MD)	Forced Flush Flag 0 Automatic flush 1 FIFO contents are flushed (including the new written data).
4 freeze (MSA/MDA)	Address Freeze Mode 0 Address is normally incremented. 1 Address is frozen.
4 cpy (MD)	Copy Mode selection 0 Write Mode 1 Copy Mode
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD/MS)	Transfer Size 00 size 0 (no data stored in the FIFO) 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
0 spriv (MSA)	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
0 dpriv (MDA)	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved

The possible write instructions are listed in the table below (unused bits should always be cleared).

**Table 41-20. Burst DMA STF Instruction List**

Binary	Assembly	Comments
00_0_0_00_00	stf r,MSA	Writes content of the SDMA general register (r) to the source address register. MSA is in incremented mode.
00_0_1_00_00	stf r,MSAIFR	Writes content of the SDMA general register (r) to the source address register. MSA is in frozen mode.
00_1_0_00_00	stf r,MSAIPF	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access. MSA is in incremented mode.
00_1_1_00_00	stf r,MSAIPFIFR	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access.
00_0_0_01_00	stf r,MDA	Writes content of the SDMA general register (r) to the destination address register. MDA is in incremented mode.
00_0_1_01_00	stf r,MDAIFR	Writes content of the SDMA general register (r) to the destination address register. MDA is in frozen mode.
00_1_0_10_00	stf r,MDISZ0IFL	No data transfers between the SDMA and MD, but all valid written data of the MD is flushed to the memory. An acknowledge or error is sent back to the SDMA core on transfer completion.
00_0_0_10_01	stf r,MDISZ8	8-bit (byte) transfer to write buffer MD
00_1_0_10_01	stf r,MDISZ8IFL	8-bit (byte) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_10	stf r,MDISZ16	16-bit (half-word) transfer to write buffer MD
00_1_0_10_10	stf r,MDISZ16IFL	16-bit (half-word) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_11	stf r,MDISZ32	32-bit (word) transfer to write buffer MD
00_1_0_10_11	stf r,MDISZ32IFL	32-bit (word) transfer to write buffer MD and flush after transfer. All valid written data of MD is flushed to memory.
00_0_1_10_00	stf r,MDICPY	No data transfer between SDMA and MD but starts a copy transfer whose length is given by the 4 LSB of r register. (Maximum burst length is eight words.)
00_0_0_11_11	stf r,MS	32-bit (word) transfer to status register MS
00_0_0_11_00	stf r,MSISZ0	Clears the error flag (if set). Other MS bits are unchanged; this instruction is also known as cref MS.

### NOTE

When a flush bit is set, the SDMA flushes the FIFO including the newly written data. An acknowledge is sent to the core before the flush completes (except if size 0 is used). The goal of this flush bit is to force a flush, but it is recommended to use it only when needed (for example, when finishing a row of pixels during 2D data transfers). Indeed, if this bit is omitted and if there are more than 32 bytes in the FIFO, a burst write access is automatically triggered.

Since all the stf r,MD instructions (including the copy mode) acknowledge the SDMA core before the store is effective (except if size 0 is used), it is recommended to perform an ldf from MS before terminating a channel in order to check the final error status. (The ldf from MS will stall the core until all the data was flushed out and the transfer status is known.)

After every stf MD instruction, the MDA is incremented by the number of bytes that are written in MD, except when it is programmed in frozen mode.

#### 41.4.12.1.6 Burst DMA Read (ldf)

When received from an ldf instruction, the function code bits are interpreted as follows, depending on the addressed register:

**Table 41-21. LDF Code Bits**

Register	7	6	5	4	3	2	1	0
MSA	s				r			
MDA								
MD			p				sz	
MS								

**Table 41-22. LDF Code Bit Field Descriptions**

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD)	Transfer Size 00 reserved 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

The table below lists the possible write instructions (unused bits should always be cleared).

**Table 41-23. Burst DMA LDF Instruction List**

Binary	Assembly	Comments
00_0_0_00_00	ldf r,MSA	Copies the source address register value into an SDMA general register. It gives the memory address of the next data that will be read with an ldf MD instruction.
00_0_0_01_00	ldf r,MDA	Copies the destination address register value into an SDMA general register. It gives the memory address where the next incoming data will be flushed.
00_0_0_10_01	ldf r,MDISZ8	8-bit (byte) read
00_1_0_10_01	ldf r,MDISZ8 PF	8-bit (byte) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_10	ldf r,MDISZ16	16-bit (half-word) read
00_1_0_10_10	ldf r,MDISZ16 PF	16-bit (half-word) read. If after this reading, and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_11	ldf r,MDISZ32	32-bit (word) read
00_1_0_10_11	ldf r,MDISZ32 PF	32-bit (word) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_11_00	ldf r,MS	Copy the status register value into an SDMA general register.

### NOTE

Read data is 0-extended before writing in the SDMA general registers. When reading the MD register, the DMA takes data from the FIFO if it is available. If part or whole data is not in the FIFO, an external burst read access is performed to provide the missing data. The SDMA is stalled as long as the required read data is not complete.

After every reading, MSA is incremented by the number of read bytes from MD FIFO, except when MSA is programmed in frozen mode.

#### 41.4.12.1.7 Prefetch/Flush and Auto-Flush Management-Burst DMA Unit

The prefetch and auto-flush management enables the SDMA RISC machine to go on while a DMA access is performed.

When the RISC core requires a prefetch ( $p = 1$ ) to the Burst DMA, it will receive an immediate transfer acknowledge before the DMA has finished the external access. This enables the RISC core to do other things like accessing another DMA machine.

The basic principle in prefetch mode is for the DMA to anticipate data reads from the SDMA RISC engine by fetching external bursts of data as soon as there is enough space in the DMA FIFO to store it. If ever the RISC engine required data that is not available in the FIFO, the read acknowledge is delayed until the data is available, but it does not have to wait until the burst completes.

The auto-flush basic principle is similar: An automatic flush is triggered every time there are eight words to be written in the FIFO. If the FIFO is full and the RISC engine requires another write, it is stalled until the burst has started and enough space was freed in the FIFO to store that new data. This means the SDMA RISC engine does not have to wait for the completion of a burst to receive its acknowledge and continue its processing.

In particular, an auto-flush is executed when DMA is in write mode and if the following is true:

- If the FIFO is empty and the first write is to a word-aligned address of any size (ex: the 2 LSB of MDA[1:0]= 0x0), the auto-flush is triggered immediately after the write of the 32'nd byte.
- If the FIFO is empty, and if MDA is an odd byte address (1, 3, 5, 7,...) and an stf MDISZ8 is executed, the byte is flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is a half-word address (2, 6, 0xA,...) and an stf MDISZ16 is executed, the two bytes of the incoming data are flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is not a word-aligned address (ex 1, 2, 3, 5, 6, 7, 9,...), and an stf MDISZ32 is executed, the first 1 to 3 bytes will be flushed up to the next word aligned address. Afterwards, an auto-flush will be triggered each time the FIFO receives 32-bytes.
- Therefore, if an stf MDISZ32 is executed with MDA equal to 0x1 and with an empty MD FIFO, the bytes located at addresses 1, 2, and 3 are flushed, and the byte located at address 4 remains in MD FIFO. This solves the misalignment issue. Additionally, the next write instructions (stf) complete the FIFO until it contains eight words; then a burst write is executed by the DMA to empty the FIFO. Protocol on the external bus does not support bursts of different data types (byte, half-word, or word).

For example, consider the case where data is written using a byte access, stf MDISZ8. The value of MDA during the very first byte write determines when the auto-flush will occur as follows:

- If MDA=0x0, the flush occurs following the write of byte 32
- If MDA=0x1, the flush occurs following the write of byte 1, byte 3 and byte 35.
- If MDA=0x2, the flush occurs following the write of byte 2 and byte 34.

- If MDA=0x3, the flush occurs following the write of byte 1 and byte 33.
- If MDA=0x4, the flush occurs following the write of byte 32

The flush command forces the DMA to flush all MD valid bytes to the EXTMC controller. An acknowledge is sent immediately to the SDMA, and any potential error is reported on a future access. It is thus essential to conclude a transfer with a last read from MS, which will stall the core until all data was flushed out and returned to the transfer status (acknowledge or error).

### NOTE

During this kind of auto-flush (which occurs only at the beginning of a misaligned write transfer) no acknowledge is sent back to the SDMA, which is stalled until a flush is completed.

## 41.4.12.1.8 Data Alignment and Endianness-Burst DMA Unit

### 41.4.12.1.8.1 Burst DMA in Read Mode

For every read access to MD, the data returned to the SDMA core and the new FIFO state depends on the MSA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is fetched externally on a 32-bit bus, but the valid bytes only are stored in the FIFO and left-aligned (for a transfer of consecutive words, it is only the first word that may be truncated). The following table shows the FIFO byte alignment strategy and the corresponding MSA, the returned data, and the new FIFO state for any access size of an internal read from MD.

**Table 41-24. FIFO Read Configuration**

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
00	x0 x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 and so on...	sz8	00 00 00 x0	01	x1 x2 x3 y0 y1 y2 y3 z0
		sz16	00 00 x0 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz32	x0 x1 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3

*Table continues on the next page...*

**Table 41-24. FIFO Read Configuration (continued)**

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
01	x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 and so on...	sz8	00 00 00 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz16	00 00 x1 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz32	x1 x2 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
10	x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 and so on...	sz8	00 00 00 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz16	00 00 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz32	x2 x3 y0 y1	10	y2 y3 z0 z1 z2 z3 t0 t1
11	x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 t2 and so on...	sz8	00 00 00 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz16	00 00 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
		sz32	x3 y0 y1 y2	11	y3 z0 z1 z2 z3 t0 t1 t2

**41.4.12.1.8.2 Burst DMA in Write Mode**

For every write access to the MD, the new FIFO state depends on the MDA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is stored in the FIFO according to the internal access size and the former MDA value. The following table shows the FIFO byte alignment strategy corresponding to MDA, as well as the new FIFO state for any access size of an internal write to MD.

**Table 41-25. FIFO Write Configuration**

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
00	tt uu vv ww ?? ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	01	tt uu vv ww x0 ?? ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	10	tt uu vv ww x0 x1 ?? ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	00	tt uu vv ww x0 x1 x2 x3 ?? ?? ?? ??
01	tt uu vv ww xx ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	10	tt uu vv ww xx x0 ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	11	tt uu vv ww xx x0 x1 ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	01	tt uu vv ww xx x0 x1 x2 x3 ?? ?? ??
10	tt uu vv ww xx yy ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	11	tt uu vv ww xx yy x0 ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	00	tt uu vv ww xx yy x0 x1 ?? ?? ?? ??
		sz32	x0 x1 x2 x3	10	tt uu vv ww xx yy x0 x1 x2 x3 ?? ??

Table continues on the next page...

**Table 41-25. FIFO Write Configuration (continued)**

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
11	tt uu vv ww xx yy zz ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	00	tt uu vv ww xx yy zz x0 ?? ?? ?? ??
		sz16	?? ?? x0 x1	01	tt uu vv ww xx yy zz x0 x1 ?? ?? ??
		sz32	x0 x1 x2 x3	11	tt uu vv ww xx yy zz x0 x1 x2 x3 ??

**NOTE**

If the FIFO mode changes from a write to a read mode, all remaining written bytes in MD are lost but no error is returned. Typically, this happens if an ldf MD is executed after stf MD instructions. Before a mode change, it is recommended to force the flush of a potential remaining byte by a stfMD|SZ0|FL instruction. In the same way, if a FIFO mode changes from a read to a write mode, all prefetched data present in the FIFO is lost and no error is returned.

**41.4.12.1.8.3 Endianness-Burst DMA Unit**

Big and Little Endian are supported by the Burst DMA, but data is always stored in MD in Big Endian.

Byte manipulation is performed when data is exchanged with an Burst controller (for example, during read or write burst accesses).

**41.4.12.1.9 Burst DMA Unit Copy Mode**

A mechanism is available to perform fast ARM-to-ARM transfers.

Data does not flow through the SDMA core: It is kept in the DMA FIFO. This mechanism is selected when writing MD with a special option in the instruction code (copy flag).

It is possible to transfer up to eight words in one SDMA instruction (this does not mean in one cycle). In this mode, every time an stf MD|CPY is executed, a read burst is executed and directly followed by a write burst transfer. Burst transfers are limited to

## Functional Description

eight words. The size of the transfer (in words)-given by the SDMA general register (4 LSB)-is also limited to eight. The following SDMA code shows how 100 bytes could be copied from the MSA address to the MDA address. This is sample code only.

### Burst DMA copy mode example

```
ldi r0,@src
stf r0,MSA // Source address setup
ldi r1,@dst
stf r1,MSA // Destination address setup
ldi r0,0x64 // data transfer counter
ldi r1,0x8

MAIN_XFER:
cmphs r0,r1 // Is r0 >= 0x8
bf LAST_XFER // If not, jump to last transfer label
stf r1,MD|CPY // Copy 8 words from MSA to MDA address.
subi r0,0x8 // Decrement counter
jmp MAIN_XFER // return to main transfer loop

LAST_XFER:
stf r0,MD|CPY
```

The main transfer loop is executed 12 times; then r0 equals 4 and the last transfer loop is run.

In this mode, an acknowledge is transmitted to the core as soon as the read burst can start; thus, a first copy instruction returns an immediate acknowledge and subsequent copy instructions will be acknowledged as soon as the previous copy has finished.

#### 41.4.12.1.10 Burst DMA Unit Error Management

Another point to consider is the management of errors.

Because the DMA immediately sends an acknowledge to the RISC core (except for the stf MS|SZ0|FLS instruction), it assumes no error will occur. If an error occurs, it is flagged (transfer error acknowledge) for the following DMA access.

This should not be a problem if the DMA is used properly. The MD accesses are meant to stall the SDMA as little as possible to optimize throughput and hide calculation time. Therefore, final access to MS should be performed before closing a channel. This access waits until any pending operation is finished in the burst DMA and gather any remaining error.

In copy mode, an error could be immediately returned to the SDMA on execution of the ldf copy or stf copy instruction. It happens when MSA or MDA are not word addresses (for example, 0[4]). This is because copy mode must only be used for transferring a large packet of aligned data.

When an error is received during a *read* transfer to the external bus, which may occur during the burst accesses, the MD FIFO contains the valid beats of the burst, and the error flag of MS is set to 2'b11 (error read burst). It is possible to read MS ("n" field) to know how much valid data remains in MD and when MD is empty (after ldf instructions). The next read MD instruction sets the MS error flag to 2'b10 (error mode), and an error is sent back to the SDMA core. In error mode, it is possible to read MSA, which gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, gives rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

In "error read burst" mode, writing MDA, MSA, or MD, or starting a copy transfer by a stf MDICOPY instruction will cancel the error mode. The following table shows when an immediate error is sent back according to the executed instruction.

**Table 41-26. Possibilities in ERROR READ BURST Mode**

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA (IU IPF) stf rn, MDA stf rn, MDICOPY	NO	Error mode is reset. MSA, MDA, or MD are updated and a DMA cycle may start. For the stf MDICOPY, a copy loop is executed.
stf rn, MS	NO	MS is updated.
ldf rn, MS ldf rn, MSA ldf rn, MDA	NO	MS, MSA, and MDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	YES/NO	Immediate error if there is no more data available for read in the FIFO.

When an error is received during a *write* transfer, the error is reported to the next DMA access. In this case, an error is sent to the SDMA core and the DMA goes to its error mode. Reading MS gives the number of bytes that remain in MD; reading MDA gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, give rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

**Table 41-27. Possibilities in ERROR Mode**

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA stf rn, MDA	Yes	Any attempt to modify MD, MSA, MDA will raise an immediate error and burst DMA remains in error mode. When address registers are write-accessed, an error is returned.

*Table continues on the next page...*

**Table 41-27. Possibilities in ERROR Mode (continued)**

DMA Instruction	Immediate Error	Comments
stf rn, MS	No	This is the only way to exit error mode. MS[9:8] must be reset by an stf MSISZ0 instruction.
ldf rn, MS ldf rn, MSA ldf rn, MDA	No	MS, MSA, and MDA could be read in error mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	Yes	Whatever the DMA direction (read or write), an ldf rn triggers an immediate error.

#### 41.4.12.1.11 Conditional Yielding-Burst DMA Unit

The standard SDMA transfer is based upon a hardware loop that has the following structure:

##### Hardware Loop

```

loop
load Rn,source           // can be ldf or ld
<computation>           // can be done through functional units
store Rn,dest            // can be st or stf
done 0                   // yield

```

This structure needs to be kept independent of the functional units' particularities regarding the context switch. However, there can be variations in the context switch's efficiency, which can depend on the number of data received up to that point, and on the data itself.

The DMA, with its 8-word burst capability, has a preferable context switch period when its address register is 8-word aligned: It is the only moment that occurs once every eight loops when the succession of bursts is not broken by the context switch. When this is not the case, a context switch requires the storing (or loading) of less than eight words, which requires separate accesses and is far less efficient. The rest of the 8-word packet is stored (or loaded) after the context restore, and this is done as separate accesses.

The proposed solution is a conditional yielding, which occurs only when the DMA is in an optimum state. It does not require any modification to the scripts. The condition is decided at the DMA level.

The DMA can be programmed in two modes-conditional or always-true-for every channel, which provides complete flexibility. By default, the DMA is not in conditional mode.

The DMA condition is computed from the FIFO fill level and the various modes, as follows:

- When copy mode is selected, regardless of the transfer direction ('read' or 'write'), the condition is always true.
- In read mode, the condition is always true.
- In write mode, the condition is true when there are four bytes or less in the FIFO; it is false when there are more than four bytes. The 4-byte limit comes from the possibility of saving those bytes as MD with absolutely no impact on the bus accesses.

The aim at conditional yielding is to avoid splitting bus accesses (especially bursts).

### 41.4.12.2 Peripheral DMA Unit Programming

The peripheral DMA unit is connected to the Multi-Layer DMA Crossbar Switch of the ARM platform.

Its goal is to perform data transfers between any blocks connected to the DMA bus of this platform. These blocks are either peripherals or memories. The peripheral DMA could be seen as the ARM platform DMA controller.

The DMA performs data transfers in three modes:

- Read mode, where data is read from peripherals or from memory connected to the ARM platform and copied in a SDMA general register.
- Write mode, where data of a general register has to be written in a peripheral or a memory.
- Copy mode, where data is read from a peripheral (or memory) at a source address (PSA) and automatically written to a peripheral (or memory) at a destination address (PDA).

In copy mode, no SDMA general register is involved as transferred data only goes through the data register of the DMA.

The peripheral DMA has three addressing modes: frozen, incremented, and decremented, as follows:

- Frozen mode-When source or destination addresses are frozen, their value is not modified after a transfer. This mode is typically used for addressing peripheral FIFOs located at a fixed address.
- Incremented mode-When source or destination addresses are in incremented mode, after every transfer they are incremented by the number of bytes transferred.
- Decrement mode-In decremented mode, addresses are decremented by the number of bytes transferred.

The peripheral DMA registers are as follows:

- Two, 32-bit address registers (PSA and PDA) that respectively contain the source address for a read access and the destination address for a write access
- A 32-bit status register (PS) that contains information on the peripheral DMA configuration, such as the number of valid bytes in the data register, the error flag, the source and destination address mode, and so on.
- A 32-bit data register (PD) that stores data involved in a data transfer

#### **41.4.12.2.1 Peripheral Source Address Register (PSA)**

The source address register contains a pointer to a source peripheral or a memory associated with the next read data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PSA) to store the address value
- A 2-bit register (stype) to store the source address mode (frozen, incremented, or decremented)
- A 2-bit register (ssize) to store the source target data path size (byte, half-word, or word)

Reading the register with the ldf instruction has no side effects and gives the address value of the next data that will be read by the SDMA during an ldf MD instruction.

Writing the source address register may have side effects. If there is valid write data in the data register and the source address is changed, the write data is discarded. If the prefetch bit is set, a DMA read cycle is issued with the new address.

When PSA is to be written, you must specify the source target address mode, providing its size (byte, half-word, or word). This enables omission of the size field in all ldf MD instructions. When DMA performs a read cycle, its size is given by the value of the PSA source size register (ssize). If source is a memory in incremented mode, first programmed in word mode (stf PSA|SZ32I), and if an SDMA script needs to read bytes from this memory, the size of the source target must be updated before executing new accesses. The source address mode and its size are given by labels added to the stf PSA instruction as described in the write section. The ssize and stype registers are part of the DMA status register (PS).

Writing to PSA may issue an immediate error if the source size is not compatible with the value to be written into the PSA register. For instance, writing a 2 in PSA and specifying that it is memory-accessed in word mode creates an immediate error.

#### **41.4.12.2.2 Peripheral Destination Address Register (PDA)**

The destination address register contains a pointer to a source peripheral or a memory associated with the next write data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PDA) to store the address value
- A 2-bit register (dtype) to store the destination address mode (frozen, incremented, or decremented)
- A 2-bit register (dsize) to store the destination target data path size (byte, half-word, or word)

Reading the register with the ldf instruction has no side effects, and gives the address value of the next data that will be written by SDMA during an stfMD instruction. Writing the destination register has no side effect. Similar to the PSA register, the destination address mode and source are specified in the stf PDA instruction and may also generate an error in case of incorrect programming.

#### 41.4.12.2.3 Peripheral Data Register (PD)

The data register of the peripheral DMA is a 32-bit register. When the destination address is correctly set up, any writing to PD will automatically flush the new input data.

The number of SDMA bytes that will be transferred is given by the PDA size register. Unlike other SDMA DMAs, PD is not a FIFO: It is not used to accumulate bytes that from the SDMA and must be packed before being sent to external memories. In read mode, and if the source address is correctly set up, an ldf instruction will empty PD. If a prefetch is required along with the instruction, the DMA will initiate a new read transfer.

Reading PD in prefetch mode only stalls the SDMA when the prefetched data is not yet available. Writing PD only stalls the SDMA if the previous write operation was not completed. As soon as the previous operation is over, the acknowledge is sent back to the SDMA RISC engine.

An error flag-part of PS-is set when an external access fails. The error is thus reported to the next SDMA instruction that involves the peripheral DMA.

#### 41.4.12.2.4 Peripheral State Register (PS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer.

Although all PS fields can be written by an stf instruction, it is recommended to access only the error bit (to reset it). Modifying other PS fields will provide an un-guaranteed DMA behavior.

The initialization value of PS is 0, and it consists of the following structure:

**Table 41-28. PS Structure**

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	ssize		stype		dsize		dtype	
W																
R	0	0	0	0	0	d	e		0	0	0	0	0	n		
W																

**Table 41-29. PS Field Descriptions**

Field	Description
31-24	Reserved
23-22 ssize	Source Target Size. Determines the size of the read transfers on the external bus. It should match the accessed device characteristics.  00 <i>reserved</i> 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
21-20 stype	Source address Mode. Determines whether PSA is incremented, decremented, or kept unmodified after every read from the external bus.  00 Frozen Mode 01 Incremented Mode 10 Decrement Mode 11 <i>reserved</i>
19-18 dsize	Destination Target Size. Determines the size of the write transfers on the external bus. It should match the accessed device characteristics.  00 <i>reserved</i> 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
17-16 dtype	Destination address Mode. Determines whether PDA is incremented, decremented, or kept unmodified after every write on the external bus.  00 Frozen Mode 01 Incremented Mode 10 Decrement Mode 11 <i>reserved</i>
15-11	Reserved

Table continues on the next page...

**Table 41-29. PS Field Descriptions (continued)**

Field	Description
10 d	Direction Flag or DMA Mode. DMA is in write mode when data was written into PD by stf PD instructions, or if a previous DMA cycle on the external bus was a write access. Writing PDA or PSA does not change the DMA mode.  DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by the SDMA with an ldf PD instruction. Reading PDA or PSA does not change the DMA mode.  0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error.  00 No error was received.  01 <i>reserved</i>  10 Error mode  11 Error read
7-3	Reserved
2-0 n	number of bytes in PD

**NOTE**

dtype, dsize, stype, and ssize are updated when PSA and PDA are written.

**41.4.12.2.5 Peripheral DMA Write (stf)-Write Mode**

When written by an stf instruction, the function code bits are interpreted as follows:

**Table 41-30. STF Code Bits**

Register	7	6	5	4	3	2	1	0
PSA	s		p	ar	am		sz	
PDA								
PD			pdsel					
PS			pssel					

**Table 41-31. STF Code Bits Field Descriptions**

Field	Description
7-6 s	Functional Unit selector  11 for Peripheral DMA

*Table continues on the next page...*

**Table 41-31. STF Code Bits Field Descriptions (continued)**

Field	Description
5 p (PSA)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
3-2 am (PSA/PDA)	Address Mode. Determines how PSA or PDA is modified after every read or write access to the PD. 00 Frozen-Address registers are not modified after the transfer. 01 Incremented-Address registers are incremented by the number of transferred bytes. 10 Decrement-Address registers are decremented by the number of transferred bytes. 11 Updated-PSA and PDA are not modified. Either address mode is not modified, but the width of the data path is updated by the sz field.
1-0 sz	Transfer Size 00 <i>reserved</i> 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
5-0 pdsel	PD access selector 001000 is the only valid option
5-0 pssel	PS access selector 111111 writes to PS 001100 only clears the error flag in PS

Due to the large number of possible stf instructions, the following table provides only a short list of all the possible write instructions:

5 p (PD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
4 cpy (PD)	Copy Mode 0 standard access 1 copy mode access
3 a	Register Set selection 0 PSA or PDA 1 PD or PS
5-0 pssel	PS access selector 111111 is the only valid option to read PS

**Table 41-35. Peripheral DMA LDF Instruction List**

Binary	Assembly	Comments
11_0_0_0_000	ldf Rn, PSA	Reads 32-bit of PSA value
11_0_1_0_000	ldf Rn, PDA	Reads 32-bit of PDA value
11_0_0_1_000	ldf Rn, PD	Reads programmed source size bytes of PD (0-extended)
11_1_0_1_000	ldf Rn, PDIPF	Reads programmed source size bytes of PD (0-extended), and starts a prefetch at PSA address.
11_0_1_1_000	ldf Rn, PDICOPY	Starts a copy transfer from the source target at the PSA address to the destination target at the PDA address. No data transmits through Rn, but Rn contents are lost (Rn is loaded with PD temporary contents that are <i>not</i> the copied data).
11_111111	ldf Rn, PS	Reads 32-bit of PS value

**NOTE**

When reading PD, size information is not important: It is embedded in the ssize field of the PSA register. If ssize is 1, 2, or 4, the one, two, or four bytes is transferred from PD to Rn. Read data is 0-extended.

**41.4.12.2.7 Peripheral DMA Unit Copy Mode**

Like burst DMA, the peripheral DMA unit has a copy mode that is used when data transfers do not involve SDMA general registers.

Data is read from the source target at a PSA address, stored in PD, and then automatically flushed to the destination target at the PDA address. Copy mode is only available for transfers that involve two targets of the same data path width.

Since copy mode is invoked with an ldf instruction, the *loaded* general purpose register loses its previous contents. (However, the new contents are unpredictable as they depend on temporary values that are seen on the external DMA bus.)

**41.4.12.2.8 Error Management**

Peripheral DMA generates two kinds of errors: the immediate error that sanctioned incorrect register programming; and the error triggered by the previous access and stored in the error flag of PS until a DMA instruction is executed.

**41.4.12.2.8.1 Immediate Errors**

The following table lists all incorrect DMA register setups.

**Table 41-36. Immediate Errors with Peripheral DMA**

Rn[1:0] values	DMA instruction	Comments
0x01 0x11	stf Rn, PSAISZ16IF stf Rn, PSAISZ16II stf Rn, PDAISZ16IF stf Rn, PDAISZ16II	If PSA points to a half-word peripheral or to a half-word address in memory, its value must be 0 modulo 2.
0x01 0x10 0x11	stf Rn, PSAISZ32IF stf Rn, PSAISZ32II stf Rn, PDAISZ32IF stf Rn, PDAISZ32II	If PSA points to a word peripheral or to a word address in memory, its value must be 0 modulo 4.
PSA[1:0]-PDA[1:0]	DMA instruction	Comments
0x01 0x10 0x11	stf Rn, PSAISZ32IU stf Rn, PDAISZ32IU	When PDA or PSA is updated and becomes a pointer to a word address in memory, its content must be 0 modulo 4.
0x01 0x11	stf Rn, PSAISZ16IU stf Rn, PDAISZ16IU	When PDA or PSA is updated and becomes a pointer to a half-word address in memory, its content must be 0 modulo 2.
Read/Write PD instruction	Comments	
stf Rn,PD ldf Rn,PD	If PDA size (dsize) has never been set up before an stf PD instruction (dsize=0) If PSA size (ssize) has never been set up before an ldf PD instruction (ssize=0)	
ldf Rn,PDICPY	Copy mode is possible only between two targets whose data path width is identical.  It is P8↔P8, P16↔P16, or P32↔P32 regardless of the way the address registers are incremented.	

#### 41.4.12.2.8.2 Data Transfer Errors

When PSA and PDA are correctly set up, the only error that may arise for an ldf PD or stf PD instruction would be the error of the previous DMA cycle.

Error handling is driven by a single consideration: When an error occurred during a data read on the DMA interface, this error should appear as a transfer error to the core when the core attempts to retrieve the data that was not successfully read from the accessed device (memory or peripheral).

When an error occurred during a write access to the DMA interface, the data is still available in PD and should not be destroyed by subsequent core accesses: The core must be warned about the error issue.

There are three error handling mechanisms for each case: [Read Error \(First Phase\)](#), [Write Error and Read Error \(Second Phase\)](#), and [Copy Mode Errors](#) handling.

#### 41.4.12.2.8.3 Read Error (First Phase)

If an error occurred during a prefetch command, the peripheral DMA enters its ERROR READ mode (PS[9:8]=11). In this mode, the error is reported on the next ldf PD instruction and writing PSA, PDA, or PD will cancel the error flag.

The block returns no error mode and instructions are normally executed (a DMA cycle may be triggered). Similarly, initiating a copy transfer will reset the error flag and start a copy transfer. The following table details which instructions can be executed in this mode.

**Table 41-37. Possibilities in ERROR READ Mode**

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA (IU IPF) stf rn, PDA ldf rn, PDICOPY	NO	Error mode is reset, PSA or PDA are updated, or a write cycle is started. For the ldf PDICOPY, a copy loop is executed.
stf rn, PS	NO	PS is updated.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Error of the previous read access is reported here and the peripheral DMA enters its ERROR mode.

#### 41.4.12.2.8.4 Write Error and Read Error (Second Phase)

The peripheral DMA enters its ERROR mode (PS[9:8]=10) when the previous DMA write cycle failed, or, as explained in [Read Error \(First Phase\)](#), when an ldf PD is executed while the block is in ERROR READ mode. When a DMA cycle failed, address registers (PSA, PDA) are not modified and continue to point to the problematic address. In ERROR mode, stf instructions may raise an immediate error, and ldf instructions will not (as detailed in the table below).

**Table 41-38. Possibilities in ERROR Mode**

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA stf rn, PDA	YES	Any attempt to modify PD, PSA, or PDA will raise an immediate error, and the peripheral DMA stays in ERROR mode. When address registers are write accessed, an error is returned.
stf rn, PS	NO	This is the only way to exit the ERROR mode. PS[3] must be reset by an stf PS instruction.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Whatever the DMA direction (read or write), an ldf rn, PD instruction will show an immediate error.

#### 41.4.12.2.8.5 Copy Mode Errors

Because copy mode is a write access that follows a read access, there are two possible cases of bus error.

When the read access incurs a bus error, the peripheral DMA behaves exactly as described in [Read Error \(First Phase\)](#) and [Write Error and Read Error \(Second Phase\)](#) : It enters its ERROR READ mode, and so on.

When the error occurred during the write access of the copy transfer, the DMA enables the core to retrieve the data that was read because it is assumed the read from the peripheral removed the data from its source device. Therefore, the data to be flushed is still in PD. Any subsequent access to PD triggers an error to the core, which should execute its error handling procedure.

Once the ERROR mode is left (after writing to PS), it is possible for the core to retrieve the data in PD with an ldf instruction or try to flush PD contents once again (for example, when the error was due to a full FIFO and the script waited for the FIFO to be emptied) with another ldf instruction in copy mode. This latter instruction detects that there is valid data in PD, tries to flush it, and thus skips the read phase of the copy instruction. This is a different behavior from the usual stf PD instruction that overwrites PD with the selected General Purpose register contents. The same mechanism can be used any time PD holds data that is not written because of a bus error on the DMA interface; when the data was written via a copy instruction, or via the usual stf PD instruction.

#### 41.4.12.2.8.6 Error Check Example

The following code illustrates an example checking for both immediate and data transfer errors on a store to the PD register. The first bdf instruction checks for an immediate error, but if a data transfer error occurred it is reported until the next instruction to access the Peripheral DMA. A second check of the error flags is done after the ldf PS instruction. The value of PS here can be ignored. The act of reading any register in Peripheral DMA while it is in an error mode that returns the error to the core to set either the SF or DF flag. Any error returned on an ldf command sets the SF flag and any error returned on an stf instruction sets the DF flag. This can create a situation as shown in the example where a bus error during a DMA write which would normally be considered as a destination fault is reported as a source fault because the error was reported to the SDMA core during an ldf instruction.

##### Peripheral DMA Error Check

```

    clrf    0           // Clear SF and DF flags
    stf     R4, PD       // Write data to memory
    bdf     error_routine // Check for immediate error from write to PD.
    ldf     r3, PS       // Read PS (PS value in R3 can be ignored)

```

```
bsf    error_routine    // Check for bus error from "stf R4,PD"
        // SF is set because it is a ldf instruction, even though
        // the original error was a destination fault
```

#### 41.4.12.2.9 Peripheral DMA Unit Prefetch/Flush Management

There is no flush bit because every time data is stored in PD by a stf PD instruction—assuming PDA is correctly programmed—it is automatically flushed to the destination.

An acknowledge is returned in the cycle of the DMA instruction, and the SDMA is only stalled by an instruction that addresses the peripheral DMA when the previous DMA access is not over.

#### 41.4.12.3 OnCE and Real-Time Debug

The On-Chip Emulation block (OnCE) is the debug interface to the SDMA.

It supports the access to all core internal devices (registers, memory, and so on), and provides a set of mechanisms that control the core. The OnCE is accessed by JTAG ports at the chip's board level, or by the host via its peripheral bus.

To reduce the size of the hardware material involved, all tasks supported by the OnCE are performed on the SDMA core. The architecture of the SDMA OnCE is relatively simple and very flexible.

The commands supported by the SDMA OnCE are listed in the following sections.

##### 41.4.12.3.1 Memory and Register Access

A set of mechanisms is provided to access SDMA memory and register locations. Both reading and writing are allowed. The access is supported if the processor is in debug mode.

Those registers can also be accessed through the ARM platform Control interface when the OnCE is controlled by the ARM platform, as described in the "Using BP" section.

##### 41.4.12.3.2 Hardware Breakpoints

An event detection unit is implemented to support memory breakpoints. The unit watches the data exchanged between the SDMA memory bus and the core.

A debug request is sent to the core when matching conditions occur. The unit supports mixed conditions based on address range, access type, and data value. Event detection unit configuration registers are memory mapped in the SDMA space (see [ARM platform Channel 0 Pointer \(SDMAARM\\_MC0PTR\)](#)): You can modify them through a regular memory access or the ARM platform control interface.

#### **41.4.12.3.3 Watchpoints**

One output pin is provided to monitor matching trigger conditions that are defined in the event detection unit.

#### **41.4.12.3.4 Software Breakpoints**

The SDMA instruction set contains a software breakpoint. Upon executing a software breakpoint instruction, the core suspends normal execution and enters debug mode.

No hardware step execution mode is implemented in the OnCE, but this feature may be implemented at the software level with this instruction.

#### **41.4.12.3.5 Core Control**

Commands are provided to monitor and control processor activity. You can halt the core, rerun the core from another address location, and get processor status.

Any hardware breakpoint on the instruction bus is not supported, but this feature may be implemented by inserting a software breakpoints program.

### **41.4.13 The OnCE Controller**

The OnCE controller receives commands from the ARM platform or from the JTAG controller. Each command is interpreted before being sent to the core.

#### **41.4.13.1 OnCE Commands**

A small set of commands supports the communication between the OnCE and the external world.

This command set enables you to perform any of the following tasks: control processor activity, save core context, and execute an SDMA instruction from the OnCE. Combined together, these tasks perform more complex commands.

A full OnCE command contains a 4-bit instruction (the OnCE command opcode) and a variable length data field (the OnCE data). During command execution, the OnCE data is transferred in a OnCE internal register before being exchanged with the SDMA. Some data values are also exported. This mechanism creates a link between the processor and the external world. Nine commands are defined: The following table presents their formats.

**Table 41-39. OnCE Command Opcode Values**

Instruction Opcode	Name	Action	Register	Data Field Size	Mode
0000	rstatus	Reads the OnCE status register	STATUS	16-bit	normal/debug
0001	dmov	Updates general register GReg1	GREG1	32-bit	debug
0010	exec_once	Runs the instruction from the SDMA instruction register	INSTRUCTION	16-bit	debug
0011	run_core	Returns to normal execution	BYPASS	1-bit	debug
0100	exec_core	Returns to normal execution via a jump instruction that specifies the new address	INSTRUCTION	16-bit	debug
0101	debug_rqst	Stops the core after execution of current instruction	BYPASS	1-bit	normal
0110	rbuffer	Reads the real time buffer	RTB	32-bit	normal/debug
0111-1110	reserved	Reserved	BYPASS	1-bit	normal/debug
1111	bypass	Bypasses TARM platform controller	BYPASS	1-bit	normal/debug

Each instruction corresponds to a specific action performed on the OnCE. The nature of the associated data field is clearly identified. The dmov command is followed by a 32-bit data value (which is a data value for the SDMA); the exec\_once and the exec\_core commands are followed by a 16-bit data value (which is an instruction for the SDMA); the rstatus command is followed by a 16-bit control value (which is the content of the OnCE status register); the rbuffer command is followed by a 32-bit data value. The debug\_rqst and the run\_core commands are followed by a single bit data field (this is a bypass value). Finally, the bypass instruction enables the SDMA JTAG TAP controller to be daisy-chained with another JTAG TAP controller. This is a JTAG-only feature. The set of commands is simple, but enables you to perform any possible task on the SDMA during a debug process.

#### 41.4.13.2 Sending Commands to the OnCE Controller

The JTAG access is the standard access to the OnCE, but sometimes the JTAG is not available to fix some bugs (if the chip is in production for instance), an additional access is then required. Therefore, one ARM platform access to the OnCE is provided.

### 41.4.13.2.1 Using the JTAG Interface

A serial access is performed through the five JTAG pins TCK, TRST, TMS, TDI, and TDO. A Test Access Port controller is provided to decode the TMS control signal.

It produces shift-enable signals (shift\_ir and shift\_dr), and updates enable signals (update\_ir and update\_dr). It is fully compliant with the IEEE 1149.1 testability (JTAG) standard.

During the shift\_ir state, the command opcode is shifted into the OnCE controller (for example, the signal from the TDI pin is shifted into the command register and the TDO pin receives the signal shifted out). After transferring the four bits of the command, an update\_ir signal is asserted and the command is decoded. The target data register is now clearly identified and the corresponding control signal is produced, as follows: bypass enable signal (bp\_en), instruction enable signal (inst\_en), data enable (data\_en), and status enable signal (stat\_en).

During the shift\_dr state, the TDI signal is shifted into one of the following target registers: bypass register (1 bit), SDMA instruction register (16 bits), SDMA data register (32 bits), or OnCE status register (16 bits). The TDO pin is connected to the output of the selected register to receive the signals shifted out.

The JTAG access is disabled when the ARM platform access is enabled.

### 41.4.13.2.2 Using the ARM platform

The ARM platform access to the OnCE is not the standard access, but it is required if the JTAG is not available.

For example, if the SDMA ROM is out of use on a chip in production, and the ARM platform needs to download new code and restart the SDMA, the OnCE can easily perform this operation. This type of debug operation justifies the use of an ARM platform access to the OnCE.

To drive the OnCE, the ARM platform uses some registers contained in the ARM platform Control block of the SDMA. These registers are accessed through the ARM platform peripheral bus. Most of these registers are connected to another register in the OnCE controller. Thus, accessing one of these registers is equivalent to accessing the associated register in the OnCE controller.

The set of registers in the ARM platform Control block is listed below:

- **ONCE\_ENB** register (1 bit, read/write)-This 1-bit register enables the ARM platform access to the OnCE. When this bit is set, the signals from the JTAG are ignored.

When it is cleared, all writing operations to the following registers through the Host Control interface are ignored. This register is reset on a JTAG reset.

- **ONCE\_CMD** register (4 bits, read/write)-This 4-bit register receives the command opcode. It is connected to the command register in the controller. A write access to this register causes the associated command to be executed on the OnCE. For example, after writing "0001" in this register, a dmov command is executed.

### NOTE

On the ARM platform side, the rstatus and bypass commands are not supported. This register is reset on a JTAG reset.

- **ONCE\_DATA** register (32 bits, read/write)-This 32-bit register is connected to the SDMA data register. This register is used when executing a dmov or rbuffer command.

### NOTE

Before requesting a dmov command, the 32-bit data to transfer must be written in the ONCE\_DATA register. At the end of the execution, the register is updated with GReg1 former value. This register is reset on a JTAG reset.

- **ONCE\_INSTR** register (16 bits, read/write)-This 16-bit register is connected to the SDMA instruction register. This register is used when executing an exec\_core or an exec\_once command.

### NOTE

Before requesting an exec\_core or an exec\_once command, the appropriate instruction must be written in the ONCE\_INSTR register. This register is reset on a JTAG reset.

- **ONCE\_STAT** register (16 bits, read only)-A read access to the ONCE\_STAT register returns the content of the OnCE status register (OSTAT). This register is read only.
- The bypass register is not useful when the ARM platform controls the OnCE, therefore no register is defined in the ARM platform Control block to access the bypass register.

#### 41.4.13.2.3 Conflicts Between the JTAG and the ARM platform Accesses

When ARM platform access to the SDMA OnCE is enabled (that is, when the bit in the ONCE\_ENB register is set), the JTAG access is disabled. This guarantees that the block is not accessed at the same time on both sides.

It is possible to check whether the JTAG access to the SDMA OnCE is enabled from the JTAG port. When the JTAG access is disabled, the SDMA TDO always returns 1. The check requires the following steps:

- Execute a dmov command from debug mode (with neither 0xffffffff nor 0x0 as dmov value: 0x5a5a5a5a is good).
- Execute another dmov command (the value here is not important).
- The returned value from the latter dmov command should be the original one if the JTAG access is enabled; if it is 0xffffffff instead of the original input value, this means the JTAG access is disabled.

### **41.4.13.3 Executing a Command from the OnCE**

All the commands defined in [OnCE Commands](#) can be accessed through the JTAG. The ARM platform can access all these commands except the rstatus command.

On the ARM platform side, the OnCE status is directly accessed by reading the ONCE\_STAT register.

#### **41.4.13.3.1 Nature of the Commands**

Two types of commands may be distinguished. First, there are two commands that do not interact with the core: rstatus and rbuffer. Those commands may be requested at any time: They do not depend on the core status.

#### **NOTE**

Each of these commands exports a data value or a status value from the SDMA.

There are also commands that interact with the core: dmov, run\_core, exec\_core, exec\_once, and debug\_rqst. These commands are core status dependent, as follows:

- During user mode only the debug\_rqst is taken into account.
- During debug mode, all these commands are taken into account except the debug\_rqst. For example, an exec\_once command requested while not in debug mode has no effect.

#### **41.4.13.3.2 Execution Request**

The SDMA starts executing a task in debug mode when requested by the OnCE controller. The execution starting time depends on the type of access used to communicate with the OnCE.

If the JTAG is used, the request is sent after decoding the `update_dr` state in the TAP controller. Therefore, always cross this state when sending a command through the JTAG. If the OnCE is driven from the ARM platform side, the request is sent after detecting a write access to the `ONCE_CMD` register. All the registers involved in this operation must be loaded first.

The following is an example of an `exec_core` command execution from the ARM platform side: After writing '010' in the `ONCE_CMD` register, the OnCE controller asks the SDMA to execute the instruction contained in the `ONCE_INSTR` register. The instruction involved should be available in the `ONCE_INSTR` register before the beginning of the execution.

#### 41.4.13.3.3 Command Execution

The following list shows the commands and details how each command is executed:

- **rstatus command execution**-The `rstatus` command exports the content of the OnCE status register (OSR). If the JTAG is used, the status information is captured in the OnCE status register during the `capture_dr` state, and shifted out after 16 TCK clock cycles in the `shift_dr` state. The `rstatus` command is not supported on the ARM platform side, but a status register is provided instead. The `rstatus` may be performed in both debug and user modes.
- **dmov command execution**-The `dmov` command accesses SDMA internal registers. Executing a `dmov` instruction exchanges the 32-bit data values between the SDMA data register and the general register `GReg1`.
- If the JTAG is used, the content of `GReg1` is captured in the SDMA data register during the `capture_dr` state, then it is shifted out after 32 TCK clock cycles in the `shift_dr` state. During the `update_dr` state, `GReg1` is updated with the new, shifted-in 32-bit data value. If the OnCE is driven from the ARM platform side, the data values contained in `GReg1` and the SDMA data register are exchanged after detecting a write access to the `ONCE_CMD` register. The `ONCE_DATA` register must therefore be loaded first.
- **exec\_once command execution**-The `exec_once` command executes the instruction loaded in the SDMA instruction register. The command may only be requested from debug mode. The SDMA returns to debug mode at the end of the execution.
- **Change of flow instructions as well as instructions that may cause a context switch are not supported:** The comprehensive list comprises `done/yield/yiedge` (except `done 5`), `BF`, `BT`, `BSF`, `BDF`, `JMP`, `JSR`, `JMPR`, `JSRR`, `RET`, and `LOOP`, as well as all the illegal instructions.

No other command should be requested before the SDMA returns to debug mode. The SDMA status (for example, whether it is in debug mode or not) can be detected by polling with the rstatus OnCE command, monitoring the debug\_mode pin, or checking the [OnCE Status Register \(SDMAARM\\_ONCE\\_STAT\)](#) register via the ARM platform control interface.

### NOTE

Most of the instructions are single-cycle, which omits the step of polling the status. Loads and stores to DMA units are typical instructions that might require this polling.

If the JTAG is used, the 16-bit instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift\_dr state. A request is sent to the core when the update\_dr state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the request is sent to the SDMA when detecting a write access to the ONCE\_CMD register. The ONCE\_INSTR register must be therefore be loaded first.

- run\_core command execution-The run\_core command leaves debug mode and resume normal program execution. The next instruction executed is the last instruction decoded before entering debug mode. Be sure to restore core context before re-running the core. This procedure is detailed in [Restoring the Context](#).
- If the JTAG is used, a 1-bit bypass value is shifted in the bypass register in the shift\_dr state. The SDMA is rerun when the update\_dr state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the core is rerun when detecting a write access to the ONCE\_CMD register.
- exec\_core command execution-The exec\_core command resumes program execution from any address. The 16-bit instruction provided with the exec\_core overwrites the last instruction decoded before entering debug mode. This command is designed to support change of flow instructions, so that a program execution can be restarted from any address. After executing an exec\_core command, the SDMA leaves debug mode. The exec\_core command is usually used with a jmp instruction.
- If the JTAG is used, the 16-bit branch instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift\_dr state. The SDMA is rerun when the update\_dr state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the SDMA reruns when detecting a write access to the ONCE\_CMD register. The ONCE\_INSTR register must therefore be loaded first. For example, to restart the SDMA from the program address 0x100, the instruction loaded should be a jump to address 0x100 instruction.
- debug\_rqst command execution-The debug\_rqst command puts the SDMA in debug mode. If the JTAG is used, a 1-bit bypass value is shifted in the bypass register during the shift\_dr state. A debug request is sent to the SDMA when the update\_dr

state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the debug request is sent when detecting a write access to the ONCE\_CMD register. When the SDMA is already in debug mode, this command is simply ignored.

- **rbuffer command execution**-The rbuffer command exports the content of the real time buffer (RTB). If the JTAG is used, the content of the real time buffer (RTB) is captured in the SDMA data register during the capture\_dr state. The register is completely shifted out after maintaining the shift\_dr state during 32 TCK clock cycles. If the OnCE is driven from the ARM platform side, the content of the RTB is captured in the ONCE\_DATA register after detecting a write access to the ONCE\_CMD register.
- **bypass command execution**-This command is only available from the JTAG interface. It enables daisy-chaining of the SDMA JTAG TAP controller with other JTAG TAP controllers. This command does not change the SDMA state and can be executed in any mode (run, debug, or sleep). It selects the bypass register of the TAP controller.

#### 41.4.13.4 Registers Descriptions

See [SDMACORE](#), and [SDMAARM](#), for detailed information on each register.

##### 41.4.13.4.1 Event Cell Counter Register (ECOUNT)

The event cell counter register is a 16-bit register that contains the number of times minus one that an event detection occurs before generating a debug request.

This register should be written before attempting to use the event detection counter during an event detection process. The event cell counter register is cleared on a JTAG reset.

##### 41.4.13.4.2 Event Cell Address Registers (EAA or EAB)

The event cell contains two address registers-the event cell address register (a), called EAA, and the event cell address register (b), called EAB. Every address register is a 16-bit register that stores a user-defined address value. This value computes one of the following address conditions: addra\_cond or addrb\_cond. Every address register is cleared on a JTAG reset.

#### 41.4.13.4.3 Event Cell Address Mask Register (EAM)

The event cell address mask register is a 16-bit register that contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before comparing addresses.

##### NOTE

There is a common address mask value for the two address comparators. If bit  $i$  of this register is set, then bit  $i$  of the address value latched from the memory bus does not influence the result of the address comparison. The event cell address mask register is cleared on a JTAG reset.

#### 41.4.13.4.4 Event Cell Data Register (ED)

The event cell data register is a 32-bit register that contains a user-defined data value. This data value is an input for the data comparator, which generates the data\_cond condition.

The event cell data register is cleared on a JTAG reset.

#### 41.4.13.4.5 Event Cell Data Mask Register (EDM)

The event cell data mask register is a 32-bit register that contains a user-defined data mask value. This mask is applied to the data value latched from the memory bus before comparing data.

Setting bit  $i$  of the event cell data mask register means that bit  $i$  of the data value latched from the address bus does not influence the result of the data comparison. The event cell data mask register is cleared on a JTAG reset.

#### 41.4.13.4.6 Real Time Buffer Register (RTB)

The real Time Buffer register is a 32-bit register that stores and retrieves run-time information without putting the SDMA in debug mode.

Refer to [Real Time Buffer](#) for more details.

#### 41.4.13.4.7 Event Control Register (ECTL)

The event cell control register is a 16-bit register that defines cell event occurrence conditions.

The event cell control register is cleared on a JTAG reset. See also [OnCE Event Detection Unit](#) for more details.

#### 41.4.13.4.8 Trace Buffer (TB)

The Trace Buffer register retrieves the information in the Trace Buffer.

See [Trace Buffer](#) for more details.

#### 41.4.13.4.9 OnCE Status Register (OSTAT)

The OnCE status register is a 16-bit register that contains processor and event detection unit status. The OSTAT is a read-only register.

Refer to [OnCE Status Register \(SDMAARM\\_ONCE\\_STAT\)](#) for detailed description of the individual fields in the OSTAT register.

The following figure shows the OSTAT structure.

**Table 41-40. OnCE Status Register (OnCE)**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PST[3:0]				RCV	EDR	ODR	SWB	MST					ECDR[2:0]		

Where PST[3:0] is the SDMA core state, RCV is set when the real-time buffer (RTB) is modified. EDR, ODR, and SWB are set, respectively, when the SDMA has entered debug mode because of an external debug request, a OnCE debug\_rqst command, or a software breakpoint. MST is set when the OnCE is controlled from the ARM platform control interface, and when ECDR is a three-flag set that shows the event cell condition(s) that put the core in debug mode. The OSTAT never provides more than one reason for entering debug mode.

There are two ways of accessing OSTAT content, as follows:

1. Send an rstatus command to the OnCE controller through the JTAG, or read the ONCE\_STAT register through the ARM platform access. Executing the rstatus command through the JTAG can be performed in both user and debug modes.
2. Perform an SDMA read access to the location in the SDMA core memory map (OSTAT register) debug mode using the exec\_once command. With this method of access, the SDMA state reflected by the PST (processor status bit) is always DATA.

The register may also be accessed by a running application.

### 41.4.13.5 JTAG Interface Requirements

Because the signals received from the JTAG (running on TCK) are transferred to the OnCE controller (running on the SDMA clock), a synchronization mechanism is required.

#### 41.4.13.5.1 TCK Speed Limitation

In the JTAG top-level layer, the TDO signal is always captured on a TCK falling edge. To guarantee a stable TDO signal from the SDMA during this operation, a falling edge detection is performed on TCK.

Before being latched in the *I* flip-flop (see [Figure 41-11](#)) on TCK falling edge, the TDO signal must be stable at the input of the flip-flop. This condition is verified if the TCK period is superior to the following delay:

*worst-case edge detection delay + negative-edge signal propagation delay + JTAG top-level logic propagation delay*

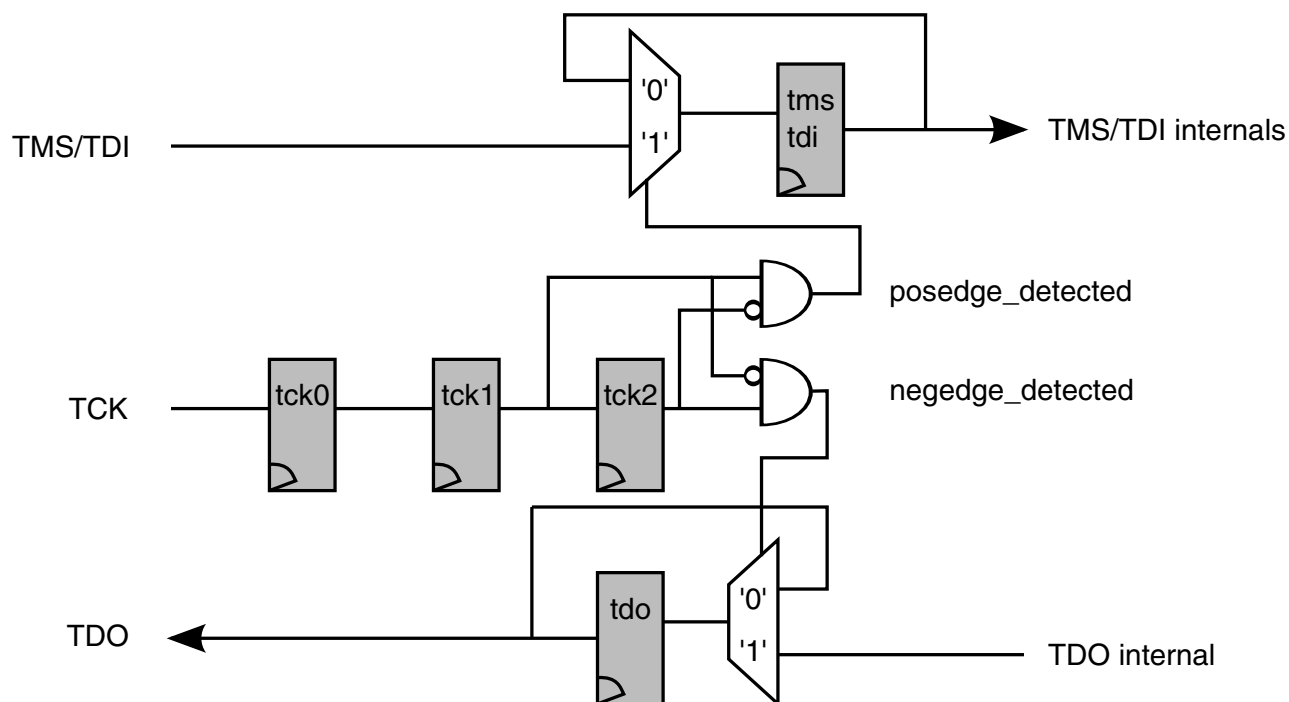

The frequency relationship,  $TCK < CLK/8$ , limitation guarantees that all operations are performed as expected.

#### 41.4.13.5.2 Synchronization Implementation

The figure found here shows the synchronization mechanism.

Flip-flops tck0, tck1, and tck2 perform falling- and rising-edge detections on TCK. They generate the posedge\_detected and negedge\_detected nets that are used to sample the TDI and TMS inputs into the respective tdi and tms flip-flops, and update the tdo flip-flop to yield the TDO output. In the design, the only signal that might go metastable is the output of the tck0 flip-flop. This signal is captured in the tck1 flip-flop and no logical operation is performed on it to minimize a metastability propagation risk.

The TDI and TMS flip-flops also cannot go metastable: The propagation time of the rising-edge detection signal through tck0, tck1, and tck2 guarantees that the TDI and TMS inputs are stable when captured in the TDI and TMS flip-flops.

**Figure 41-11. OnCE Synchronization Layer**

The following figure shows synchronization timings. It takes three CLK clock cycles to synchronize TDI on the SDMA clock.

**Figure 41-12. Synchronization Timings**

### 41.4.13.5.3 JTAG Controller Start-Up Recommended Procedure

To ensure correct TAP controller initialization, it is recommended to use the following procedure:

1. Assert JTAG reset TRSTB (for example, set low).
2. Set TMS low.
3. Wait for 1 TCK clock.
4. Release JTAG reset TRSTB (for example, set high).
5. Wait for a minimum of five TCK cycles.

## 41.4.14 Using the OnCE

This section provides the elements necessary to run the OnCE during a debug process.

In addition to the basic set of commands described in [OnCE Commands](#), more complex commands can be built to meet users' requirements.

### 41.4.14.1 Activating Clocks in Debug Mode

For power consumption issues, some clocks in the SDMA are disabled when not needed.

This is the case for instances when the SDMA is in sleep mode. Clock gating management depends on the interface used to control the OnCE.

- For the JTAG access, the SDMA clock gating must be turned off via the `clk_gating_off` input.
- For the ARM platform access, the SDMA clock gating is automatically turned off when the ARM platform access is enabled (see [OnCE Enable \(SDMAARM\\_ONCE\\_ENB\)](#)).

### 41.4.14.2 Getting the Current Status

Most of the commands the OnCE supports have an impact on the status of the SDMA.

It is not permissible to request the execution of an instruction on the SDMA from the OnCE while the SDMA is not in debug mode. Such a violation may cause unpredictable behavior, and it might be necessary to reset the SDMA.

Therefore, the value of the PST bits provided in the OnCE status register should always be checked before sending any request to the SDMA.

### 41.4.14.3 Methods of Entering Debug Mode

A debug request may be asserted at any time, but it is not always taken into account immediately. Debug mode cannot be entered in the middle of an instruction, or during the save or restore states of a context switch.

The request is ignored when the core is already in debug mode. Refer to [Figure 41-4](#), which shows all possible transitions to the debug state, as there are several ways to enter debug mode.

#### 41.4.14.3.1 External Debug Request During Reset

To enter debug mode after exiting reset, the external debug line has to be maintained high. This line is handled by the JTAG top-level block.

##### NOTE

The SDMA detects the debug requests only if the SDMA clock is running (see [Activating Clocks in Debug Mode](#)). The debug request line should not be maintained high when the SDMA is in debug mode.

##### NOTE

The debug\_rqst command (from the OnCE command set) is not supported during system reset.

#### 41.4.14.3.2 Debug Request During Normal Activity

During normal activity, the SDMA enters debug mode when the following is true:

1. If the debug request line from the JTAG top-level is asserted, or
2. If the OnCE controller receives a debug\_rqst command.

The debug\_rqst command can be sent by the JTAG access or by an access on the ARM platform side (if the ARM platform access is enabled).

#### 41.4.14.3.3 Software Breakpoint Instruction

The SDMA enters debug mode at the end of the execution of a software breakpoint instruction. This instruction must be inserted in program flow executed by the core.

#### 41.4.14.3.4 Event Detection Unit Matching Condition

If the event detection is enabled, a debug request is sent to the core after detecting a matching condition on the SDMA memory bus.

See [OnCE Event Detection Unit](#) for more details.

#### 41.4.14.4 Executing Instructions in Debug Mode

The OnCE supports a mechanism to execute instructions in debug mode. If the SDMA is in debug mode, then the `exec_once` command can be used to execute an SDMA instruction from the OnCE controller. The SDMA returns to debug mode at the end of each execution.

Some instructions are not supported by the `exec_once` command: `done`/`yield`/`yiedge` (except `done 5`), `BF`, `BT`, `BSF`, `BDF`, `JMP`, `JSR`, `JMPR`, `JSRR`, `RET`, and `LOOP`, as well as all the illegal instructions are not supported.

#### NOTE

While instructions are executed in debug mode from the OnCE, the program counter of the SDMA is not incremented.

#### 41.4.14.5 Command Sequences Examples

This section provides examples of command sequences that run the SDMA in debug mode. These sequences are available for both the ARM platform and JTAG accesses.

The following presents the syntax used in this section. The data field provided with each command is put in parenthesis with the command name. A '-' is used if the data field provided is a *don't care* value.

```
my_command(data_field);           // executing my_command with a data field
my_command(-);                   // executing my_command with a don't care data field
```

The value returned by the command (if there is one) is referred by an assignment. In case the value returned by the command is not used, the assignment is omitted. For an ARM platform access, the value returned (it is always a data value) is obtained by reading back into the SDMA data register.

```
data_out = my_command(data_in); // returning a data value
```

To clarify the syntax, the instructions' opcodes are referred to by their names. In practice, use the corresponding 16-bit encoding.

### 41.4.14.5.1 Getting the SDMA Status

#### NOTE

Before executing any command that affects the SDMA (like `dmov` or `exec_once`), check that the SDMA is in debug mode.

Use the following snippet:

```
rstatus();           // read SDMA status until the SDMA is in debug mode
...
rstatus();
```

If the SDMA is not in debug mode, then a debug request must be generated. In this case, the SDMA enters debug mode at the end of the execution of the current instruction. Use this snippet:

```
debug_rqst(-);      // debug request
```

In the following sections, it is assumed that the SDMA was successfully put into debug mode.

### 41.4.14.5.2 Saving the Context

The first debug task is to save the SDMA context, which is the content of the eight general-purpose registers, the loop and PC-related registers, and the flags.

Use the general register `GReg[1]` as an intermediate register to export the entire context of the SDMA.

The following example shows how to save `GReg[0]`, `GReg[1]`, `GReg[2]` and `GReg[3]`. The sequence of commands used to export additional general registers is very similar to this.

Save `GReg[0]`, `GReg[1]`, `GReg[2]`, and `GReg[3]`

```
GReg1_data = dmov(-);           // the value exported is the content of
GReg[1]                                     // puts the content of GReg[0] into
exec_once("mov GReg1,GReg0");
GReg[1]
GReg0_data = dmov(-);           // the value exported is the content of
GReg[0]                                     // puts the content of GReg[2] into
exec_once("mov GReg1, GReg2");
GReg[1]
GReg2_data = dmov(-);           // the value exported is the content of
GReg[2]                                     // puts the content of GReg[3] into
exec_once("mov GReg1, GReg3");
GReg[1]
GReg3_data = dmov(-);           // the value exported is the content of
GReg[3]
```

Get the value of the internal flags (SF, DF, T, and LM), of the loop related registers (EPC and SPC), and of the PC-related registers (PC and RPC). Use a `done 5`, which is the formatting instruction dedicated to the debug. This instruction formats the flags and the values contained in the registers. It also writes the resulting values into the channel

context memory. It should not be used when entering debug from the IDLE state (for example, with no active channel script running on the SDMA), because it will update a channel context that may belong to any channel.

```
exec_once("done 5"); // formatting the value of flags and registers
```

At this point, the channel context should be up-to-date in memory, and debug operations should now be possible. However, the context can be exported with the following instructions:

### Exporting the Context

```
dmov(ctx_base_addr); // loading GReg[1] with the channel
context base address
exec_once("ld GReg0, (GReg1,0)"); // get RPC-PC into GReg0
exec_once("ld GReg1, (GReg1,1)"); // get SPC-EPC into GReg1
Loop_data = dmov(-); // read back the value of Loop registers
exec_once("mov GReg1, GReg0"); // puts the PC info into GReg1
PC_data = dmov(-); // reads back the content of the PC registers
```

After this sequence of operations, the entire SDMA context is exported via the OnCE.

### 41.4.14.5.3 Restoring the Context

At this point in the operation, restore the context of the SDMA. It can be different from the original context located in memory, and the content previously saved into the debugging application via the OnCE.

The example found hereshows how it is possible to modify the current channel context.

### Modifying the Current Channel Context

```
dmov(Loop_data); // put Loop former value into GReg[1]
exec_once("mov GReg0, GReg1"); // copy to GReg[0]
dmov(PC_data); // put PC former value into GReg[1]
exec_once("mov GReg2, GReg1"); // copy to GReg[2]
dmov(ctx_base_addr); // put channel context base address into
GReg[1]
exec_once("st GReg0, (GReg1,1)"); // restore Loop context
exec_once("st GReg2, (GReg1,0)"); // restore PC context
```

Once the context in memory is the desired context (with or without applying the previous instruction sequence), it can be restored to the *real* PC and loop registers in the SDMA core:

```
exec_once("cpShReg"); // restore flags and PC & loop related registers
```

After this command, the SDMA core PC, RPC, SPC, EPC registers, as well as the flags contain the same data as what is stored in the context RAM for the current channel.

The following example shows how to restore the context of general registers GReg[0], GReg[1], GReg[2] and GReg[3].

### Restoring the General Register Context

```

dmov(GReg3_data); // put GReg[3] restore value in GReg[1]
exec_once("mov GReg3, GReg1"); // restore GReg[3]
dmov(GReg2_data); // put GReg[2] restore value in GReg[1]
exec_once("mov GReg2, GReg1"); // restore GReg[2]
dmov(GReg0_data); // put GReg[0] restore value in GReg[1]
exec_once("mov GReg0, GReg1"); // restore GReg[0]
dmov(GReg1_data); // restore GReg[1]

```

At this point, it is possible to restart the normal program execution.

### NOTE

Every SDMA core general register value can be modified by a mov instruction, which makes modification of these registers easy during debug. Unfortunately, there is no such instruction as a mov to directly modify the contents of either PCU register or flag (PC, RPC, SPC, EPC, T, LM, SF, or DF). The cpShReg instruction is meant to provide a means for changing these register contents via the context memory.

#### 41.4.14.5.4 Accessing the Memory

In the example shown here, it is assumed that the SDMA context is entirely saved. If true, it is permissible to modify the general purpose registers during debugging activity.

To perform a memory read access, the target address is stored via the OnCE in GReg[1], then the load instruction is executed on the SDMA (the data loaded from the memory overwrites the address contained in GReg[1]), and then the result value is read back via the OnCE.

```

macro READ:          dmov(target_addr); // put the target
address in GReg[1]   exec_once("ld GReg1, (GReg1,0)"); // execute the
load instruction     res_data = dmov(-); // exports the result
data value

```

For a memory write access, the target address is written in GReg[0], and the value to store is written in GReg[1]. Then the store instruction is executed on the SDMA.

```

macro WRITE:          dmov(target_addr); // puts the
target address in GReg[1] exec_once("mov GReg0, GReg1"); // puts the target
address in GReg[0]     dmov(target_data); // puts the target
data in GReg[1]        exec_once("st GReg1, (GReg0,0)"); // performs the
store operation

```

This sequence is shown as an example; however, many other sequences are possible.

### NOTE

This sequence of commands can also be applied to memory-mapped registers.

#### 41.4.14.5.5 Resuming Program Execution

Before resuming program execution, it is assumed that the SDMA context is properly restored. There are two ways to restart the SDMA.

Start by executing the last instruction fetched before entering debug mode, as follows.

```
run_core(-); // resume execution from where we stopped before
```

If necessary, restart the execution from a different address. In this case, use the `exec_core` command. The data field provided with this command must be the encoding of a jump instruction.

```
exec_core("jmp start_addr"); // rerun the SDMA from another address
```

In these two examples, the SDMA exits debug mode and keeps executing the code fetched from the memory.

#### 41.4.14.5.6 Single Stepping in RAM

To execute a program step-by-step from the RAM, insert software breakpoints in the program flow at appropriate places so that the SDMA only executes one instruction before returning to debug mode.

First, read the next instruction to execute in the RAM. Then, depending on the value of this instruction, compute the address where a software breakpoint instruction should be inserted. The instruction at the corresponding address must be saved, and, the software breakpoint instruction is inserted. After restarting the SDMA, there is only one instruction executed before meeting the software breakpoint.

The following example shows the macro functions `READ` and `WRITE`, which correspond to the sequence of commands (described above) used to access the memory.

#### NOTE

The data read from the memory are 32-bit values, while the instructions are 16-bit values only. This is why it is best to only use addresses divided by two when accessing the memory.

#### READ and WRITE Macro Functions

```
next_instr = READ(run_addr/2); // read the next instruction to execute
// the tool now has to compute the address where the breakpoint
// instruction should be inserted, this address is the "bkpt_addr"
instr_save = READ(bkpt_addr/2); // save the instruction before
overwriting // store the bkpt instruction
STORE("bkpt instruction",bkpt_addr/2);
in memory
exec_core("jmp run_addr"); // rerun the SDMA
rstatus(-); // wait for the SDMA to enter debug mode
...
rstatus(-);
```

```
STORE(instr_save,bpkt_addr/2);  
overwritten
```

```
// restore the instruction
```

In case of branched conditional instructions, a breakpoint instruction should be written at the two possible target addresses.

#### 41.4.14.5.7 Single Stepping in ROM

No single-step mechanism is supported in ROM. The program code can be loaded in the RAM, where the single-step mechanism can be executed.

#### 41.4.14.6 OnCE Event Detection Unit

The event detection unit watches signals from the data memory bus (DMBUS), which the SDMA core uses to access its RAM, ROM, and memory mapped registers.

A debug request is sent to the OnCE controller when user-defined conditions on address and/or data values are true.

**Figure 41-13. Event Detection Unit**

A counter, provided with the detection cell, is decreased after an event detection. A debug request is sent to the core only when the counter reaches the value of 0. It is possible to disable the use of the counter if a debug request has to be generated after each event detection.

The event cell is the basic block that supports hardware breakpoints on an address value and/or data values coming from the SDMA memory bus. The trigger condition that generates the debug request is a mixed condition based on those values.

The following figure shows the event cell architecture. The event cell contains the address (stored in the memory address register) and the data (stored in the memory data register) used during the last memory access. There are some user-defined reference values located in memory mapped registers—the event cell addresses, the event cell address mask, the event cell data, and the event cell data mask. These registers are accessed by standard load/store instructions just like regular memory locations.

**Figure 41-14. Event Cell Architecture**

To define a memory breakpoint, three conditions are taken into account: The first two conditions are comparisons of the current memory address with user-defined reference addresses (these conditions are called addressA and addressB). The third condition consists of a comparison between the data received on the DMBUS and a user-defined reference data (this condition is called data). An intermediate address condition is set to express a dependency between addressA and addressB conditions.

#### 41.4.14.7 Clock Gating and Reset

This section details how to use the clocks and handle the reset signals.

##### 41.4.14.7.1 Clocks

Because the SDMA uses clock gating to save power, it is necessary to disable the clock gating and force the clocks to be enabled when using the OnCE.

When the OnCE is accessed through its JTAG interface, clock gating must be disabled outside the SDMA via a dedicated SDMA input port `clk_gating_off`. The reason why detection is not performed automatically by the SDMA internal hardware is that it would cost power to monitor activity on the JTAG interface.

When the OnCE is accessed through the ARM platform Control interface, clock gating is automatically turned off. This is done when bit 0 of the ONCE\_ENB register (see [OnCE Enable \(SDMAARM\\_ONCE\\_ENB\)](#)) is set. A write access to this register is possible even when the OnCE clock is not running. If the ARM platform access is used, the bit in the ONCE\_ENB register must be set before any attempt to access any other OnCE register.

#### 41.4.14.7.2 Resets

The OnCE reset is different from the SDMA main reset.

Normally, activating the SDMA reset while keeping the OnCE reset inactive (when possible) enables you to reset the core without having to reprogram the OnCE.

### 41.4.14.8 Real Time Features

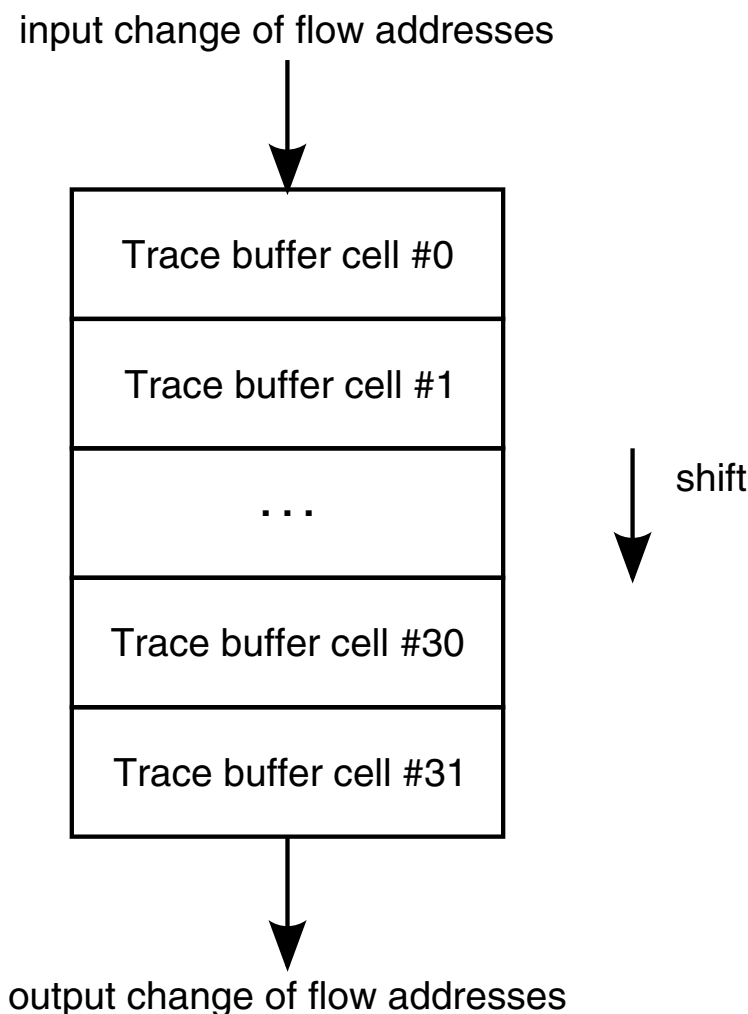

To rebuild the skeleton of a program execution, it is necessary to store the addresses of the program instructions where jumps are taken: A trace buffer is therefore provided. A real time buffer has also been added to receive data values written during a program execution.

The content of this register may be exported through JTAG ports without stopping the core.

#### 41.4.14.8.1 Trace Buffer

The Trace Buffer is a 32-stage buffer that contains appropriate information to identify the 32 last changes of flow detected during a program execution.

The following figure shows an overview of the Trace Buffer.

**Figure 41-15. Trace Buffer**

Each cell of the trace buffer contains two reference addresses and a flag. The flag is set when the addresses stored in the cell correspond to a valid change of flow; otherwise, the flag is cleared. The three most significant bits are unused.

After every change of flow detection, the address of current instruction and the address of the target instruction are stored at the top of the Trace Buffer (cell #0). The flag in the cell is set to indicate that a valid change of flow was detected. Former cell values are shifted one level down. The Trace Buffer contains the 32 last changes of flow. All the flags are reset on a software or a hardware reset, and after each transition from debug mode to user mode.

A memory mapped register of SDMA core, the Trace Buffer register (TB), is provided to read the content of the Trace Buffer. This operation should be done in debug mode. Performing a read access to the Trace Buffer register returns the content of the bottom of the Trace Buffer (cell #31). After every read access, the trace buffer is shifted one level down, and the flag at the top of the trace buffer is cleared.

A typical OnCE command sequence that retrieves the oldest change-of-flow information is as follows:

```
exec_once("mov r1, TB");           // stores the oldest change-of-flow in
GReg1                               // retrieves GReg1 contents
dmov(-);
```

This sequence requires the SDMA to be put in debug mode.

#### 41.4.14.8.2 Real Time Buffer

The Real Time Buffer register (RTB) is a memory mapped register that can be accessed as a regular memory location by the SDMA core during program execution. This register is located in the OnCE.

Executing an `rbuffer` command (see [The OnCE Controller](#) for further details) exports the content of this register through JTAG ports.

When a write access is performed at the memory location corresponding to the RTB, the receive flag (for example, the RCV bit) is set in the OnCE Status Register (OSR). This flag is cleared at the end of the execution of a `rbuffer` command.

#### NOTE

Every write access to the RTB memory location updates the RTB register even if the RCV flag is set. The RTB is cleared on a JTAG reset.

#### 41.4.14.8.3 Emulation Pin

The `debug_matched_event` emulation pin reflects the matching condition status detected by the Event Detection Unit.

Since it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

#### 41.4.14.8.4 Real-Time Debug Outputs

The table found here shows the debug signals that are available at the SDMA boundaries. Their availability at chip boundaries depends on the project.

**Table 41-41. Real-Time Debug Output Pins**

Pin	Description
debug_core_state[3:0]	<p>The core_state bits reflect the state of the SDMA core.</p> <ul style="list-style-type: none"> <li>• The "Program" state is the usual instruction execution cycle.</li> <li>• The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st).</li> <li>• The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions).</li> <li>• The "Change of Flow in Loop" state is used when an error causes a hardware loop exit.</li> <li>• The "Debug" state means the SDMA is in debug mode.</li> <li>• The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf).</li> <li>• In "Sleep" modes, no script is running (this is the core idle state); the "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 is executed (boot operation).</li> <li>• The "in Sleep" states are the same as above except they do not have any corresponding channel: they are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode.</li> </ul> <p>0 Program  1 Data  2 Change of Flow  3 Change of Flow in Loop  4 Debug  5 Functional Unit  6 Sleep  7 Context Switch Saving Channel  8 Program in Sleep  9 Data in Sleep  10 Change of Flow in Sleep  11 Change of Flow in Loop in Sleep  12 Debug in Sleep  13 Functional Unit in Sleep  14 Sleep after Reset  15 Context Switch Restoring Channel</p>
debug_yield	<p>Pulse that is active when a yield (done 0) or a yieldge (done 1) instruction is executed.</p> <p>0 -  1 yield/yieldge executed</p>

*Table continues on the next page...*

**Table 41-41. Real-Time Debug Output Pins (continued)**

Pin	Description
debug_core_run	Active when the SDMA core is executing instructions. 0 Debug or sleep mode 1 Run mode
debug_event_channel_sel	Indicates if debug_event_channel displays current channel or last received event 0- debug_event_channel[5:0] gives the number of the current channel 1- debug_event_channel[5:0] gives the number of the last received event
debug_event_channel[5:0]	Gives the number of any DMA request as soon as it is received or the number of the current channel.  The value of debug_event_channel_sel indicates if debug_event_channel displays the current channel or last received event. The signal debug_event_channel_sel must be observed to determine what information is provided on debug_event_chanel at any given time.
debug_pc[13:0]	Program Counter value; it has a meaning when the core is in run mode.
debug_mode	Set when the core is in debug. 0 - 1 Core is in debug
debug_bus_error	Set when an error was received during a load or a store (ld, st, ldf, or stf instruction) and registered in SF or DF flag. 0 No error during last load/store 1 Error during last load/store

*Table continues on the next page...*

**Table 41-41. Real-Time Debug Output Pins (continued)**

Pin	Description
debug_bus_device[4:0]	Indicates the device or functional unit that is accessed by the current instruction. The debug_bus_device output is always valid when in sleep mode, debug mode, or executing any instruction that does not access the functional units or the memory mapped devices, "no access" is output.

*Table continues on the next page...*

**Table 41-41. Real-Time Debug Output Pins (continued)**

Pin	Description
debug_bus_rwb	Indicates the direction of the access given by debug_bus_device 0 Write access (st or stf) 1 Read access (ld or ldf)
debug_matched_dmbus	Pulse indicating the OnCE event detection unit has detected a match on the data bus during an access to memory (RAM or ROM), a memory mapped register or a peripheral that is hooked to the SDMA. 0 - 1 data bus match detected
debug_rtbuffer_write	Pulse indicating when the real-time buffer is written by the core. 0 - 1 RTB was modified
debug_evt_chn_lines[7:0]	Eight lines that generate short pulses when DMA requests are received or channels are (re)started. Every line is controlled through two parameters defined in registers <a href="#">Cross-Trigger Events Configuration Register 1 (SDMAARM_XTRIG_CONF1)</a> (as described in <a href="#">SDMAARM</a> ). The following two parameters are available for every line: <ul style="list-style-type: none"> <li>• CNF-Indicates what is monitored on the line: 0 for a channel start, 1 for a DMA request reception</li> <li>• NUM[ 5:0]-Gives the number of the DMA request or channel to monitor</li> </ul>

The matched\_event emulation pin reflects the matching condition status detected by the Event Detection Unit. Because it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

All real-time debug outputs are disabled by default (for example, they are stuck to 0) to avoid power consumption when they are not used. They are enabled when bit 11 (RTDOBS) of the [Configuration Register \(SDMAARM\\_CONFIG\)](#) is set. Signals provided to the system JTAG controller for SDMA debug mode status will also be enabled when the *clk\_gating\_off* input is asserted.

## 41.5 Instruction Set

### 41.5.1 Instruction Encoding

This section presents a short summary of the instruction codes. All context switch instructions are listed for information only; they cannot function properly out of the context switch routine.

x...x - don't care  
 rrr - destination/source general register  
 sss - additional source general register  
 bbb - general register used as address base register  
 dddd - address displacement  
 nnnnn - bit number  
 uuuuuuuu - function unit command bits  
 pppppppp - branch displacement (signed)  
 iiiiii - 8-bit immediate  
 jjj - control bit to clear  
 ff - flag to clear  
 00000jjj00000000 - done (done,yield,wait)  
 00000jjj00000001 - notify

(continued)**

Inst ruct ion	Description	Page
LSL 1	Logical Shift Left by 1 Bit	LSL1 (Logical Shift Left by 1 Bit)
LSR 1	Logical Shift Right by 1 Bit	LSR1 (Logical Shift Right by 1 Bit)
MOV	Logical Move	MOV (Logical Move)
NOT IFY	Notify to ARM platform	NOTIFY (Notify to ARM platform)
OR	Logical OR	OR (Logical OR)
ORI	Logical OR with Immediate Value	ORI (Logical OR with Immediate Value)
RET	Return from Subroutine	RET (Return from Subroutine)
REV B	Reverse Byte Order	REVB (Reverse Byte Order)
REV BLO	Reverse Low Order Bytes	Reverse Low Order Bytes(REVBLO)
ROR 1	Rotate Right by 1 Bit	ROR1 (Rotate Right by 1 Bit)
ROR B	Rotate Right by 1 Byte	RORB (Rotate Right by 1 Byte)
SOF TBK PT	Software Breakpoint	SOFTBKPT (Software Breakpoint)
ST	Store Register	ST (Store Register)
STF	Store Register in Functional Unit	STF (Store Register in Functional Unit)
SUB	Subtract	SUB (Subtract)
SUB I	Subtract with Immediate	SUBI (Subtract with Immediate)
TST	Test with Zero	TST (Test with Zero)
TSTI	Test Immediate	TSTI (Test Immediate)
XOR	Logical Exclusive OR	XOR (Logical Exclusive OR)
XOR I	Exclusive OR with Immediate	XORI (Exclusive OR with Immediate)

### 41.5.2.1 ADD (Addition)

#### Operation:

$$\text{GReg}[\text{r}] \leftarrow \text{GReg}[\text{s}] + \text{GReg}[\text{r}]$$

$$\text{T} \leftarrow (\text{GReg}[\text{r}] == 0)$$

#### Assembler:

## Instruction Set

Syntax: `add r,s`

Example: `add 0,3`

ADD GReg[3] and GReg[0] and store the result in GReg[0]

CPU Flags: T

Cycles: 1

Description: Performs the ADDition of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*. The T flag is set if the result of the operation is 0. It is cleared if the result is not 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

### 41.5.2.2 ADDI (Add with Immediate Value)

**Operation:**

$\text{GReg}[r] \leftarrow \text{GReg}[r] + \text{immediate}$

$T \leftarrow (\text{GReg}[r] == 0)$

**Assembler:**

Syntax: `addi r,immediate`

Example: `add 6,112`

ADD GReg[6] and decimal value 112 and store the result in GReg[6]

CPU Flags: T

Cycles: 1

Description: Adds a 0-extended immediate value to a general register; stores the result in the general register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

### 41.5.2.3 AND (Logical AND)

**Operation:**

$\text{GReg}[r] \leftarrow \text{GReg}[s] \ \& \ \text{GReg}[r]$

**Assembler:**

## Instruction Set

Syntax: `and r,s`

Example: `and 1,2`

AND GReg[1] and GReg[2] and store the result in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

### 41.5.2.4 ANDI (Logical AND with Immediate Value)

**Operation:**

$\text{GReg}[r] \leftarrow \text{GReg}[r] \& \text{immediate}$

**Assembler:**

Syntax: `andi r,immediate`

Example: `andi 7,45`

AND GReg[7] and decimal value 45 and store the result in GReg[7]

CPU Flags: unaffected

Cycles: 1

**Description:** Performs an AND between a 0-extended immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

**Instruction Format**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	1	r	r	r	i	i	i	i	i	i	i	i

**Instruction Fields:**

**rrr - register field:**

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

**iiiiiii - immediate value:**

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

### 41.5.2.5 ANDN (Logical AND NOT)

**Operation:**

$\text{GReg}[r] \leftarrow \sim \text{GReg}[s] \ \& \ \text{GReg}[r]$

**Assembler:**

Syntax: `andn r,s`

Example: `andn 3,4`

## Instruction Set

AND GReg[3] and NOT GReg[4] (bit inverted) and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the negation of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format:

**Table 41-43. Instruction Format**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	<i>r</i>	<i>r</i>	<i>r</i>	1	0	1	1	0	<i>s</i>	<i>s</i>	<i>s</i>

Instruction Fields:

rrr /sss - destination register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

### 41.5.2.6 ANDNI (Logical AND with Negated Immediate Value)

**Operation:**

$\text{GReg}[r] \leftarrow \text{GReg}[r] \& \sim\text{immediate}$

**Assembler:**

Syntax: `andni r,immediate`

Example: `andni 0,2`

AND GReg[0] and decimal value -3 (inverted 32-bit value 2) and store the result in GReg[0]

CPU Flags: unaffected

Cycles: 1

**Description:** Performs an AND between the negation of a 0-extended 8-bit immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

**Instruction Format**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	0	r	r	r	i	i	i	i	i	i	i	i

**Instruction Fields:**

**rrr - register field:**

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

**iiiiiii - immediate value:**

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

### 41.5.2.7 ASR1 (Arithmetic Shift Right by 1 Bit)

**Operation:**

$\text{GReg}[r] : \{b_{31}, b_{30}, \dots, b_1, b_0\} \leftarrow \text{GReg}[r] : \{b_{31}, b_{31}, b_{30}, \dots, b_1\}$

**Assembler:**

Syntax: `asr1 r`

Example: `asr1 3`

divide by 2 the signed value of GReg[3] and store the result in GReg[3]

## Instruction Set

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any general register to the right and keep the same sign: The left bit (bit 31) is kept untouched.

Instruction Format:

**Table 41-44. Instruction Format**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

### 41.5.2.8 BCLRI1 (Bit Clear Immediate)

**Operation:**

$\text{GReg}[r] : \{b_{31}, \dots, b_{(i+1)}, 0, b_{(i-1)}, \dots, b_0\} \leftarrow \text{GReg}[r] : \{b_{31}, \dots, b_{(i+1)}, b_{(i)}, b_{(i-1)}, \dots, b_0\}$

**Assembler:**

Syntax: `bclri r,i`

Example: `bclri 1,12`

clear bit 12 in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Clear the bit of register r specified by the 5-bit immediate field

## Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	1	i	i	i	i	i

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiii - immediate value:

00000 - 0

00001 - 1

...

11110 - 30

11111 - 31

### 41.5.2.9 BDF (Conditional Branch if Destination Fault)

#### Operation:

if (DF == 1) PC ← PC + 1 + displacement else PC ← PC + 1

#### Assembler:

Syntax: bdf label

Example: bdf LLL

Jump to LLL if DF is set, or go to the next instruction if DF is cleared; the displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

## Instruction Set

**Description:** If flag DF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag DF is cleared, no jump is performed: The next instruction is located at the next PC address.

### Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	1	p	p	p	p	p	p	p	p

### Instruction Fields:

pppppppp - signed displacement field:

00000000 - 0

00000001 - 1

...

01111110 - 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 - (-2)

11111111 - (-1)

## 41.5.2.10 BF (Conditional Branch if False)

### Operation:

```
if (T == 0)
```

```
PC ← PC + 1 + displacement
```

```
else
```

```
PC ← PC + 1
```

### Assembler:

Syntax: bf label

Example: bf LLL

Jump to LLL if T is cleared, or go to the next instruction if T is set. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is cleared, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is set, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```

00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)

```

### 41.5.2.11 BSETI (Bit Set Immediate)

**Operation:**

$$\text{GReg}[r] : \{b_{31}, \dots, b_{(i+1)}, 1, b_{(i-1)}, \dots, b_0\} \leftarrow \text{GReg}[r] : \{b_{31}, \dots, b_{(i+1)}, b_{(i)}, b_{(i-1)}, \dots, b_0\}$$

**Assembler:**

Syntax: `bseti r,i`

Example: `bseti 6,5`

Set bit 5 in GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Sets bit number i in the selected General Register.

## Instruction Set

### Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	0	i	i	i	i	i

### Instruction Fields:

#### rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

#### iiii - bit number field:

00000 - 0

00001 - 1

...

11110 - 30

11111 - 31

## 41.5.2.12 BSF (Conditional Branch if Source Fault)

### Operation:

if (SF == 1) PC ← PC + 1 + displacement else PC ← PC + 1

### Assembler:

Syntax: bsf label

Example: bsf LLL

Jump to LLL if SF is set, or go to the next instruction if SF is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

**Description:** Conditional branch: If flag SF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag SF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)
```

### 41.5.2.13 BT (Conditional Branch if True)

#### Operation

```
if (T == 1)
    PC ← PC + 1 + displacement
else
    PC ← PC + 1
```

#### Assembler

```
Syntax: bt label

bt LLL
```

Jump to LLL if T is set, or go to the next instruction if T is cleared. The displacement value is calculated by the assembler.

## Instruction Set

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	1	p	p	p	p	p	p	p	p

pppppppp - signed displacement field:

```
00000000 - 0
00000001 - 1
...
01111110 - 126
01111111 - 127
10000000 - (-128)
10000001 - (-127)
...
11111110 - (-2)
11111111 - (-1)
```

### 41.5.2.14 BTSTI (Bit Test immediate)

#### Operation:

$T \leftarrow \text{GReg}[r] : b(i)$

#### Assembler:

Syntax: `btsti r,i`

Example: `btsti 2,29`

Test bit 29 in GReg[2] and copy its value in flag T

CPU flags: T

Cycles: 1

Description: T is loaded with the value of bit number i from the selected general register.

## Instruction Format:

**Table 41-45. Instruction Format**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	1	i	i	i	i	i

## Instruction Fields:

## rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

## iiii - bit number field:

0000 - 0

0001 - 1

...

11110 - 30

11111 - 31

**41.5.2.15 CLRF (Clear ARM platform flags)****Operation:**

if (ff%2 == 0)

SF ← 0

if (ff/2 == 0)

DF ← 0

**Assembler:**

Syntax: clrf ff

Example: clrf 2

## Instruction Set

Clear flag SF and keep flag DF unchanged

CPU Flags: SF, DF

Cycles: 1

Description: Clears a selection of the ARM platform fault flags: SF, DF, both SF and DF or none can be cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	f	f	0	0	0	0	0	1	1	1

Instruction Fields:

ff - flags field:

00 - clear SF and clear DF

01 - clear DF

10 - clear

SF 11 - no clear

## 41.5.2.16 CMPEQ (Compare for Equal)

**Operation:**

$T \leftarrow (GReg[s] == GReg[r])$

**Assembler:**

Syntax: cmpeq r,s

Example: cmpeq 7,5

Compare GReg[7] and GReg[5] and set flag T if they are equal

CPU flags: T

Cycles: 1

Description: Subtracts the destination general register *r* from the source general register *s*, and sets T if the result is 0, clears T if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	1	s	s	s

**Instruction Fields:****rrr / sss - register field:**

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

**41.5.2.17 CMPEQI (Compare with Immediate for Equal)****Operation:** $T \leftarrow (GReg[r] == \text{immediate})$ **Assembler:**

Syntax: cmpeqi r,immediate

Example: cmpeqi 2,13

Compare GReg[2] and decimal value 13 and set flag T if they are equal

**CPU Flags:** T**Cycles:** 1

**Description:** Subtracts the 0-extended 8-bit immediate value from the general register, and sets T if the result is 0, clears T if the result is not 0. The immediate value is the low-order byte of the instruction.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	1	r	r	r	i	i	i	i	i	i	i	i

**Instruction Fields:****rrr - destination register field:**

000 - GReg[0]

## Instruction Set

001 - GReg[1]  
010 - GReg[2]  
011 - GReg[3]  
100 - GReg[4]  
101 - GReg[5]  
110 - GReg[6]  
111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0  
00000001 - 1  
...  
11111110 - 254  
11111111 - 255

### 41.5.2.18 CMPHS (Compare for Higher or Same)

#### Operation:

$T \leftarrow (GReg[r] \geq GReg[s])$

#### Assembler:

Syntax: `cmphs r,s`

Example: `cmphs 0,1`

Compare GReg[0] and GReg[1] and set flag T if GReg[0] is higher than or equal to GReg[1]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is higher than or equal to the source general register *s*, clears T otherwise. The comparison is unsigned.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	1	s	s	s

**Instruction Fields:****rrr / sss - register field:**

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

**41.5.2.19 CMPLT (Compare for Less Than)****Operation:** $T \leftarrow (GReg[r] < GReg[s])$ **Assembler:**Syntax: `cmplt r,s`Example: `cmplt 7,4`

Compare GReg[7] and GReg[4] and set flag T if GReg[7] is lower than GReg[4]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is lower than the source general register *s*, clears T otherwise. The comparison is signed.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	0	s	s	s

**rrr / sss - register field:**

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

## Instruction Set

011 - GReg[3]  
100 - GReg[4]  
101 - GReg[5]  
110 - GReg[6]  
111 - GReg[7]

### 41.5.2.20 cpShReg (Update Context of PCU Registers and Flag)

#### Assembler:

Syntax: cpShReg

CPU Flags: none

Cycles: 1

Description: SF, RPC, T, PC, LM, EPC, DF, and SPC registers are updated according to the value of their corresponding bits in the context memory. This instruction must only be used in debug mode via the OnCE. It reverses the done 5 operation.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	0	1	1	1	0	0	0	1	0

### 41.5.2.21 DONE (DONE, Yield)

#### Operation:

```
if (jjj&6 == 2) HE[CCR] ← 0
```

```
if (jjj == 3) HI[CCR] ← 1
```

```
if (jjj == 4) EP[CCR] ← 0
```

```
if ((jjj == 0) && (NCP > CCP)) CCR ← NCR
```

```
else if ((jjj == 1) && (NCP >= CCP))
```

```
CCR ← NCR
```

```
else
```

```
CCR ← NCR
```

(CCR stands for Current Channel Register; NCR stands for Next Channel Register)

**Assembler:**

Syntax: done jjj

Example: done 3

Clear HE bit for the current channel, send an interrupt to the ARM platform for the current channel and reschedule.

CPU Flags: Unaffected

Cycles: Variable if a context switch is done, 1 otherwise

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required. Sends an interrupt to the corresponding ARM platform by setting the appropriate flag, if required (HI for the corresponding channel number). Reschedules according to the mode and the NCP (Next Channel Priority) and CCP (Current Channel Priority) values. According to the scheduling decision, the NCR (Next Channel Register) is copied to the CCR (Current Channel Register) and channel contexts are switched. If several channels with the same highest priority are pending, they are ordered by their number from 31 down to 0. The higher number is selected (for example, channel 26 is selected if channels 3, 12, 14, and 26 with the same highest priority are pending). If no flag is modified, the reschedule can allow the replacement of the current channel by another channel with a priority strictly greater than the current channel priority (yield). Or, it can allow the replacement of the current channel by another channel with a priority greater than or equal to the current channel priority (yieldge). In the latter case, the selected channel will always be the first one with the same priority, starting from channel number 31 down to channel 0 (the current channel does not belong to the set of selectable channels).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	0

jjj - Channel Flags field:

000 - No channel flags affected: Reschedule only if the next channel priority is greater than current channel priority (yield)

001 - No channel flags affected: Reschedule only if the next channel priority is greater than or equal to the current channel priority (yieldge)

010 - Clear HE for the current channel and reschedule 011 - Clear HE, set HI for the current channel and reschedule 100 - Clear EP for the current channel and reschedule

101 - Reserved for debug to copy relevant registers into context memory

110 - RESERVED

111 - RESERVED

For the scheduling rules, refer to [Scheduler Functional Description](#). Every possible done instruction is further described as follows:

- done 0/yield is executed by a channel script when it accepts preemption by a higher priority channel;
- done 1/yieldge is executed by a channel script when it accepts preemption by a higher priority channel and it also accepts a roll-up with other channels that have the same priority;
- done 2 is executed by a channel script that was triggered by a ARM platform start via the [Channel Start \(SDMAARM\\_HSTART\)](#) register, when its task is completed and it requires termination;
- done 3 is executed by a channel script that was triggered by a ARM platform start via the [Channel Start \(SDMAARM\\_HSTART\)](#) register, when its task is completed, it requires termination and it needs to trigger an interrupt to the ARM platform upon closure;
- done 4 is executed by a channel script that was triggered by a DMA request, when its task is completed and it requires termination;
- done 5 is used in debug mode only; it copies the PCU registers and flags to the context memory of the current channel;

#### 41.5.2.22 ILLEGAL (ILLEGAL Instruction)

##### Operation:

$PC \leftarrow 0001$

##### Assembler:

Syntax: `illegal`

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the Illegal instruction routine located at address 0001. All unauthorized instructions result in an Illegal instruction behavior; however, the ILLEGAL instruction must be used to guarantee software compatibility with future versions of the SDMA.

Instruction Format

**Table 41-46. Instruction Format**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1

### 41.5.2.23 JMP (Unconditional Jump Immediate)

#### Operation:

$PC \leftarrow \text{absolute\_address}$

#### Assembler:

Syntax: `jmp label`

Example: `jmp LLL`

The assembler translates the label to the exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaaaaa - address field:

0000000000000000 - 0

0000000000000001 - 1

...

1111111111111110 - 16382

1111111111111111 - 16383

### 41.5.2.24 JMPR (Unconditional Jump)

#### Operation:

$PC \leftarrow GReg[r]$

## Instruction Set

### Assembler:

Syntax: `jmp r`

Example: `jmp 0`

Jump to address stored in GReg[0]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained in a General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	0

### Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

## 41.5.2.25 JSR (Unconditional Jump to Subroutine Immediate)

### Operation:

$RPC \leftarrow PC + 1$

$PC \leftarrow \text{absolute\_address}$

### Assembler:

Syntax: `jsr r`

Example: `jsr LLL`

Jumps to subroutine starting at LLL; the assembler translates the label to exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine located at the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaaa - address field:

0000000000000000 - 0

0000000000000001 - 1

...

111111111111110 - 16382

111111111111111 - 16383

## 41.5.2.26 JSRR (Unconditional Jump to Subroutine)

**Operation:**

$RPC \leftarrow PC + 1$

$PC \leftarrow GReg[r]$

**Assembler:**

Syntax: jsrr r

Example: jsrr 5

Jumps to subroutine located at address stored in GReg[5]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine at address contained in a General Register

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	1

**Instruction Fields:****rrr - register field:**

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

### **41.5.2.27 LD (Load Register)**

**Operation:**

$\text{GReg}[r] \leftarrow [\text{GReg}[b] + \text{displacement}]$

if (transfer\_error)

SF  $\leftarrow$  1

else

SF  $\leftarrow$  0

**Assembler:**

Syntax: `ld r, (b, displacement)`

Example: `ld 1, (2, 23)`

Loads data into GReg[1]; the data is located at address obtained by adding decimal value 23 to GReg[2]

CPU Flags: SF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to fetch on the DM bus. The data received from the bus is stored in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	r	r	r	d	d	d	d	d	b	b	b

rrr / bbb - register field:

000 - GReg[0]

001 - GReg[1]

...

111 - GReg[7]

dddd - displacement value:

00000 - 0

00001 - 1

...

11111 - 31

### 41.5.2.28 LDF (Load Register from Functional Unit)

#### Operation:

GReg[r] ← [fu\_address]

if (transfer\_error)

SF ← 1

else

SF ← 0

fu\_address is an 8-bit field and depends on addressed functional unit

#### Assembler:

Syntax: ldf r, fu\_address

Example: ldf 0, 13

Loads data coming from the Burst DMA register MD into GReg[0]; it is a 32-bit access with no prefetch

CPU Flags: SF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

## Instruction Set

**Description:** Sends an 8-bit address on the Functional Unit Bus (FU bus) and stores the data received from the bus in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

### Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	0	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the LDF instruction usage with each functional unit:

- [Burst DMA Read \(ldf\)](#) for Burst DMA
- [Peripheral DMA Read \(ldf\)-Read Mode](#) for Peripheral DMA

### Instruction Fields:

#### rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

#### ffffff - functional unit source register and action (unspecified values are reserved):

00000000 - MSA

00000100 - MDA

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word

00001100 - MS

00101001 - MD byte - prefetch

00101010 - MD halfword - prefetch

00101011 - MD word - prefetch

01000000 - DSA

11000000 - PSA  
 11001000 - PD  
 11010000 - PDA  
 11011000 - PD in copy mode (rrr contents are lost)  
 11101000 - PD - prefetch next data  
 11111111 - PS

### 41.5.2.29 LDI (Load Register with Immediate Value)

#### Operation:

$\text{GReg}[r] \leftarrow \text{immediate}$

#### Assembler:

Syntax: `ldi r,immediate`

Example: `ldi 6,1`

loads decimal value 1 into GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Stores a 0-extended immediate value in a General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	r	r	r	i	i	i	i	i	i	i	i

#### Instruction Fields:

##### rrr - register field:

000 - GReg[0]  
 001 - GReg[1]  
 010 - GReg[2]  
 011 - GReg[3]  
 100 - GReg[4]  
 101 - GReg[5]

## Instruction Set

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

### 41.5.2.30 LDRPC (Load from RPC to Register)

#### Operation:

GReg[r] ← RPC

#### Assembler:

Syntax: ldrpc r

Example: ldrpc 3

copies RPC to GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Stores the contents of the RPC in a General Register. That instruction may be used to have more than one level of subroutines.

#### Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	1	0

#### Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

```

101 - GReg[5]
110 - GReg[6]
111 - GReg[7]

```

### 41.5.2.31 LOOP (Hardware Loop)

#### Operation:

```

if (ff%2 == 0)
    SF ← 0
if (ff/2 == 0)
    DF ← 0
if ((GReg[0] == 0) || (SF == 1) || (DF == 1))
    PC ← PC + loop_size + 1
else
{
    SPC ← PC + 1
    EPC ← PC + loop_size + 1
    LM ← 1
    PC ← PC + 1
}

```

during every instruction execution in the loop:

```

if ((SF == 1) || (DF == 1))
{
    LM ← 0
    PC ← EPC
}
else if ((PC + 1) == EPC)
{
    GReg[0] ← GReg[0] - 1
    if (GReg[0] == 0)
    {
        LM ← 0
        PC ← EPC
    }
}

```

## Instruction Set

```
    }  
    else  
        PC ← SPC  
    }  
else  
    PC ← nextPC(instruction)
```

after the execution of the last instruction of the loop body:

```
if (GReg[0] == 0)  
    T ← 1  
else  
    T ← 0
```

### Assembler:

Syntax: `loop n{,ff}`

Example: `loop 3,1`

Executes GReg[0] times the instructions comprised between PC+1 and PC+3 (included); ff=1 clears the DF flag before starting the loop. When omitted, the ff field is set to 0 (clearing both SF and DF).

CPU Flags: LM[1:0], T

Cycles: 2 when the loop count (GReg[0]) is 0 or SF or DF is set at loop start, 1+1 when the loop starts but exits abnormally (SF or DF set inside the loop which adds 1 cycle to the offending load or store to jump to EPC), 1 when the loop is executed normally

Description: The loop instruction executes a sequence of instructions several times. The number of times is given by the contents of GReg[0], the loop counter. SDMA will jump to the first instruction after the end of the loop if the value in GReg[0] is 0. Otherwise the SDMA enters loop mode. It sets the most significant bit of the LM flag that will only be reset once the last instruction of the last loop is executed. The instructions in the loop are executed GReg[0] times. The management of fault flags (SF and DF) is as follows. When entering the hardware loop, SF and DF can be cleared according to the ff field of the instruction. After that operation, if any flag is still set the loop will not be executed. The SDMA will jump to the first instruction after the end of the loop without entering loop mode. During the execution of the loop, if any fault flag is set by a LD, LDF, ST, or STF instruction, the SDMA will immediately exit loop mode and jump to the first instruction after the end of the loop. In that case, GReg0 is not decremented for that last piece of the loop body execution (even if the SF or DF flag is set at the last instruction of the loop body). The T flag reflects the state of GReg[0] after the end of the loop, which is an indicator of the complete execution of the loop. If the loop exited because of an error (SF

or DF set), GReg[0] will not be 0 at the end of the loop, hence T will be cleared. If the loop executes without fault, GReg[0] will be 0 at the end of the loop, hence T will be set. The boundary case when a source or destination fault occurs at the last instruction of the last loop is considered as an anticipated exit of the loop, which causes the T flag to be cleared. If the last instruction executed before leaving the hardware loop also tries to modify the T flag, the flag is updated according to the value of GReg[0], NOT according to the result of the last executed instruction.

#### Limitations:

1. 1. Jump instructions (JMP, JMPR, JSR, JSRR, BF, BT, BSF, BDF) are not allowed inside the hardware loop.
2. 2. GReg[0] cannot be written to inside the hardware loop (it can be read).
3. 3. The empty loop (0 instruction in the body) is forbidden.
4. 4. If GReg[0] == 0 at the start of the loop, which causes a jump to EPC, the T flag is not updated.

#### Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	0	f	f	n	n	n	n	n	n	n	n

#### Instruction Fields:

ff - flags field:

00 - clear SF and clear DF

01 - clear DF

10 - clear SF

11 - no clear

#### nnnnnnnn - loop size

00000000 - empty loop: forbidden value

00000001 - 1 instruction in the loop

00000010 - 2 instructions in the loop

...

11111111 - 255 instructions in the loop

### 41.5.2.32 LSL1 (Logical Shift Left by 1 Bit)

#### Operation:

## Instruction Set

$\text{GReg}[r] : \{b30, \dots, b1, b0, 0\} \leftarrow \text{GReg}[r] : \{b31, b30, \dots, b1, b0\}$

### Assembler:

Syntax: `lsl1 r`

Example: `lsl1 2`

multiplies by 2 the value in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the left. The right bit (bit 0) is set to 0. No overflow is detected by the hardware.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	1

### Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

## 41.5.2.33 LSR1 (Logical Shift Right by 1 Bit)

### Operation:

$\text{GReg}[r] : \{0, b31, b30, \dots, b1\} \leftarrow \text{GReg}[r] : \{b31, b30, \dots, b1, b0\}$

### Assembler:

Syntax: `lsr1 r`

Example: `lsr1 4`

divides by 2 the unsigned value contained in GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the right. The left bit (bit 31) is set to 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	1

Instruction Fields:

rrr - destination register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

### 41.5.2.34 MOV (Logical Move)

**Operation:**

$\text{GReg}[r] \leftarrow \text{GReg}[s]$

**Assembler:**

Syntax: `mov r,s`

Example: `mov 4,0`

copies GReg[0] to GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Move the contents of the source General Register *s* to the destination General Register *r*.

Instruction Format

## Instruction Set

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	0	1	s	s	s

## Instruction Fields:

### rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

## 41.5.2.35 NOTIFY (Notify to ARM platform)

### Operation:

```
if (jjj & 4 == 0)
{
    if (jjj&2 == 2)
        HE[CCR] ← 0
    if (jjj&1== 1)
        HI[CCR] ← 1
}
else if (jjj == 4)
    EP[CCR] ← 0
else
```

(CCR stands for Current Channel Register)

### Assembler:

Syntax: notify jjj

Example: notify 3

clears the HE bit for the current channel and sends an interrupt to the Host for the current channel

CPU Flags: Unaffected

Cycles: 1

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required, sends an interrupt to the corresponding ARM platform by setting the appropriate flag if required (HI for the corresponding channel number).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	1

jjj - Channel Flags field:

000 - unused

001 - set HI for the current channel

010 - clear HE for the current channel

011 - clear HE, set HI for the current channel

100 - clear EP for the current channel

101 - RESERVED

110 - RESERVED

111 - RESERVED

## 41.5.2.36 OR (Logical OR)

**Operation:**

$\text{GReg}[r] \leftarrow \text{GReg}[s] \mid \text{GReg}[r]$

**Assembler:**

Syntax: `or r,s`

Example: `or 3,6`

ORs GReg[3] and GReg[6] and stores the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

## Instruction Set

**Description:** Performs the OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	1	s	s	s

**Instruction Fields:**

rrr / sss - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

### 41.5.2.37 ORI (Logical OR with Immediate Value)

**Operation:**

$\text{GReg}[r] \leftarrow \text{GReg}[r] \mid \text{immediate}$

**Assembler:**

Syntax: `ori r,immediate`

Example: `ori 1,56`

ORs GReg[1] and the decimal value 56 and stores the result in GReg[1]

CPU Flags: unaffected

Cycles: 1

**Description:** Performs an OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	1	r	r	r	i	i	i	i	i	i	i	i

## Instruction Fields:

### rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

### iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

## 41.5.2.38 RET (Return from Subroutine)

### Operation:

PC  $\leftarrow$  RPC

### Assembler:

Syntax: ret

CPU Flags: Unaffected

Cycles: 2

Description: Return from subroutine.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

### 41.5.2.39 REVB (Reverse Byte Order)

#### Operation:

$$GReg[r] : \{B3, B2, B1, B0\} \leftarrow GReg[r] : \{B0, B1, B2, B3\}$$

#### Assembler:

Syntax: `revb r`

Example: `revb 5`

reverses bytes order in GReg[5]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse the byte order of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	0

#### Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

### 41.5.2.40 Reverse Low Order Bytes(REVBLO)

#### Operation:

$$GReg[r] : \{B3, B2, B0, B1\} \leftarrow GReg[r] : \{B3, B2, B1, B0\}$$

**Assembler:**

Syntax: revblo r

Example: revblo 0

reverses low order bytes in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse both low order bytes of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	1

**Instruction Fields:**

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

**41.5.2.41 ROR1 (Rotate Right by 1 Bit)****Operation:**

$$\text{GReg}[r] : \{b0, b31, b30, \dots, b1\} \leftarrow \text{GReg}[r] : \{b31, b30, \dots, b1, b0\}$$
**Assembler:**

Syntax: ror1 r

Example: ror1 3

rotates bits to the right in GReg[3]

CPU Flags: Unaffected

## Instruction Set

Cycles: 1

Description: Rotate the bits of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	0

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

## 41.5.2.42 RORB (Rotate Right by 1 Byte)

**Operation:**

$\text{GReg}[r] : \{B0, B3, B2, B1\} \leftarrow \text{GReg}[r] : \{B3, B2, B1, B0\}$

**Assembler:**

Syntax: `rorb r`

Example: `rorb 2`

rotates bytes to the right in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bytes of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	1	0

## Instruction Fields:

### rrr - register field:

000 - GReg[0]  
 001 - GReg[1]  
 010 - GReg[2]  
 011 - GReg[3]  
 100 - GReg[4]  
 101 - GReg[5]  
 110 - GReg[6]  
 111 - GReg[7]

## 41.5.2.43 SOFTBKPT (Software Breakpoint)

### Operation:

Stops the current script and enters debug mode

### Assembler:

```
softbkpt
```

CPU Flags: Unaffected

Description: When the core executes this instruction, it has the same effect as receiving a debug request from the OnCE or via the external debug request input: the script execution halts, the PCU enters its debug state and waits for the OnCE commands that are described in [OnCE and Real-Time Debug](#).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

## 41.5.2.44 ST (Store Register)

### Operation:

```
[GReg[b] + displacement] ← GReg[r]
```

```
if (transfer_error)
```

## Instruction Set

DF ← 1

else

DF ← 0

## Assembler:

Syntax: st r, (b, displacement)

Example: st 7, (0, 9)

stores the value from GReg[7] into memory at address obtained by adding decimal value 9 to GReg[0]

CPU Flags: DF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to store on the DM bus. The data sent on the bus comes from the source General Register r. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	r	r	r	d	d	d	d	d	b	b	b

## Instruction Fields:

rrr / bbb - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

dddd - displacement value:

00000 - 0

00001 - 1

...

11111 - 31

### 41.5.2.45 STF (Store Register in Functional Unit)

#### Operation:

```
[fu_address] ← GReg[r] 0
```

```
if (transfer_error) 0
```

```
DF ← 1 0
```

```
else 0
```

```
DF ← 0
```

fu\_address is an 8-bit field

#### Assembler:

Syntax: `stf r, fu_address`

Example: `stf 3, 0x2B`

stores the 32-bit contents of GReg[3] to the Burst DMA register MD; waits until the flush to external memory is completed

CPU Flags: DF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and sends the contents of the source General Register r on the bus. If an error occurs during the transfer, the flag DF is set, else it is cleared.

**Table 41-47. Instruction Format**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	1	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the STF instruction usage with each functional unit:

- [Burst DMA Write \(stf\)](#) for Burst DMA
- [Peripheral DMA Write \(stf\)-Write Mode](#) for Peripheral DMA

Instruction Fields:

rrr - register field:

## Instruction Set

000 - GReg [0]

001 - GReg [1]

010 - GReg [2]

011 - GReg [3]

100 - GReg [4]

101 - GReg [5]

110 - GReg [6]

111 - GReg [7]

ffffff - functional unit destination register and action (unspecified values are reserved):

00000000 - MSA in incremented mode

00000100 - MDA in incremented mode

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word

00001100 - clear MS error flag

00001111 - MS

00010000 - MSA in frozen mode

00010100 - MDA in frozen mode

00011000 - MD in copy mode - number of words in rrr

00100000 - MSA in incremented mode - start prefetch

00101000 - MD no data - flush

00101001 - MD byte - flush

00101010 - MD halfword - flush

00101011 - MD word - flush

00110000 - MSA in frozen mode - start prefetch

11000001 - PSA in frozen mode - 8-bit data width  
11000010 - PSA in frozen mode - 16-bit data width  
11000011 - PSA in frozen mode - 32-bit data width  
11000101 - PSA in incremented mode - 8-bit data width  
11000110 - PSA in incremented mode - 16-bit data width  
11000111 - PSA in incremented mode - 32-bit data width  
11001000 - PD  
11001001 - PSA in decremented mode - 8-bit data width  
11001010 - PSA in decremented mode - 16-bit data width  
11001011 - PSA in decremented mode - 32-bit data width  
11001100 - clear PS error flag  
11001101 - PSA data width becomes 8-bit  
11001110 - PSA data width becomes 16-bit  
11001111 - PSA data width becomes 32-bit  
11010001 - PDA in frozen mode - 8-bit data width  
11010010 - PDA in frozen mode - 16-bit data width  
11010011 - PDA in frozen mode - 32-bit data width  
11010101 - PDA in incremented mode - 8-bit data width  
11010110 - PDA in incremented mode - 16-bit data width  
11010111 - PDA in incremented mode - 32-bit data width  
11011001 - PDA in decremented mode - 8-bit data width  
11011010 - PDA in decremented mode - 16-bit data width  
11011011 - PDA in decremented mode - 32-bit data width  
11011101 - PDA data width becomes 8-bit  
11011110 - PDA data width becomes 16-bit  
11011111 - PDA data width becomes 32-bit  
11100001 - PSA in frozen mode - 8-bit data width - prefetch data

11100010 - PSA in frozen mode - 16-bit data width - prefetch data  
 11100011 - PSA in frozen mode - 32-bit data width - prefetch data  
 11100101 - PSA in incremented mode - 8-bit data width - prefetch data  
 11100110 - PSA in incremented mode - 16-bit data width - prefetch data  
 11100111 - PSA in incremented mode - 32-bit data width - prefetch data  
 11101001 - PSA in decremented mode - 8-bit data width - prefetch data  
 11101010 - PSA in decremented mode - 16-bit data width - prefetch data  
 11101011 - PSA in decremented mode - 32-bit data width - prefetch data  
 11101101 - PSA data width becomes 8-bit - prefetch data  
 11101110 - PSA data width becomes 16-bit - prefetch data  
 11101111 - PSA data width becomes 32-bit - prefetch data  
 11111111- PS

## 41.5.2.46 SUB (Subtract)

### Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] - \text{GReg}[s]$

$T \leftarrow (\text{GReg}[r] == 0)$

### Assembler:

Syntax: `sub r,s`

Example: `sub 4,7`

SUBtracts GReg[7] from GReg[4] and stores the result in GReg[4]

CPU Flags: T

Cycles: 1

Description: Subtracts the source General Register s from the destination General Register r, and stores the result in the destination General Register r. The T flag is set if the result of the operation is 0; it is cleared if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	0	s	s	s

## Instruction Fields:

rrr / sss - register fields:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

### 41.5.2.47 SUBI (Subtract with Immediate)

#### Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] - \text{immediate}$

$T \leftarrow (\text{GReg}[r] == 0)$

#### Assembler:

Syntax: `sub r,immediate`

Example: `sub 1,255`

SUBtracts decimal value 255 from GReg[1] and stores the result in GReg[1]

CPU Flags: T

Cycles: 1

Description: Subtracts a 0-extended 8-bit immediate value from a General Register; stores the result in the General Register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	0	r	r	r	i	i	i	i	i	i	i	i

## Instruction Fields:

## Instruction Set

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

### 41.5.2.48 TST (Test with Zero)

#### Operation:

$T \leftarrow ((\text{GReg}[s] \ \& \ \text{GReg}[r]) \neq 0)$

#### Assembler:

Syntax: `tst r,s`

Example: `tst 2,3`

ANDs GReg[2] and GReg[3] and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of the source General Register s and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	0	s	s	s

**Instruction Fields:****rrr / sss - register field:**

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

**41.5.2.49 TSTI (Test Immediate)****Operation:** $T \leftarrow ((\text{GReg}[r] \ \& \ \text{immediate}) \neq 0)$ **Assembler:**Syntax: `tsti r,immediate`Example: `tsti 5,13`

ANDs GReg[5] and decimal value 13 and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of a 0-extended 8-bit immediate value and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	r	r	r	i	i	i	i	i	i	i	i

**Instruction Fields:****rrr - destination register field:**

000 - GReg[0]

## Instruction Set

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

## 41.5.2.50 XOR (Logical Exclusive OR)

### Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[s] \wedge \text{GReg}[r]$

### Assembler:

Syntax: `xor r,s`

Example: `xor 0,3`

XORs GReg[0] and GReg[3] and stores the result in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the eXclusive OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

### Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	0	s	s	s

### Instruction Fields:

rrr / sss - register field:

000 - GReg[0]  
 001 - GReg[1]  
 010 - GReg[2]  
 011 - GReg[3]  
 100 - GReg[4]  
 101 - GReg[5]  
 110 - GReg[6]  
 111 - GReg[7]

### 41.5.2.51 XORI (Exclusive OR with Immediate)

#### Operation:

$\text{GReg}[r] \leftarrow \text{GReg}[r] \wedge \text{immediate}$

#### Assembler:

Syntax: `xori r,immediate`

Example: `xor 7,5`

XORs GReg[5] and decimal value 5 and stores the result in GReg[7]

CPU Flags: Unaffected

Cycles: 1

Description: Performs an eXclusive OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	0	r	r	r	i	i	i	i	i	i	i	i

#### Instruction Fields:

rrr - register field:

000 - GReg[0]  
 001 - GReg[1]  
 010 - GReg[2]  
 011 - GReg[3]

## Software Restrictions

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiii - immediate value:

00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255

### 41.5.2.52 YIELD, YIELDGE (DONE, Yield)

By default, unsupported assembler syntax. Can be aliased to the corresponding done instructions (yield = done 0; yieldge = done 1). Refer to the done instruction description [DONE \(DONE, Yield\)](#).

## 41.6 Software Restrictions

### 41.6.1 Unsupported Burst DMA Access Sequence

The SDMA does not support triggering a pre-fetch followed by a flush of the Burst DMA without reading or writing any data. If the flush occurs while the background pre-fetch DMA operation is still in progress, it could result in un-defined behavior.

An example of the sequence which could result in undefined results is shown in the following example:

Instruction sequence not supported

```
stf r1, MSA|PF      ; Update source address, triggers data pre-fetch in the
                    ; background
mov R0,R0            ; Execute multiple assembly instructions, none of which
                    ; read
mov R0,R0            ; or write data to/from MD
stf MD|SZ0|FL        ; Flush FIFO without writing data. If the pre-fetch is still
                    ; in progress when this instruction is executed, there
                    ; could be undefined operation
```

A work-around to avoid any undesirable results is to first read MD to ensure the pre-fetch is complete before the flush is attempted.

Work-Around to previous example

```

stf r1, MSA|PF      ; Update source address, triggers data pre-fetch.
mov R0,R0            ; Execute multiple assembly instructions, none of which
                    ; read
mov R0,R0            ; or write data to/from MD
ldf r2, MD           ; dummy read of MD to ensure pre-fetch is complete
                    ; before the next instruction
stf MD|SZ0|FL        ; Flush FIFO without writing data

```

## 41.7 Application Notes

### 41.7.1 Data Structures for Boot Code and Channel Scripts

SDMA boot code downloads the different channel contexts and the scripts that will be executed on SDMA channels during the application.

The boot code is run after reset when channel 0 is started by the ARM platform. The boot code is also known as channel 0 script.

The boot code is based on the Channel Control Block (CCB) and Buffer Descriptor (BD) mechanisms that are data structures located into the ARM platform memory space. With these data structures, it is possible to instruct SDMA to download scripts and contexts but also to dump a context or a script to a destination data buffer. Channel scripts also use the CCB and BD data structures to pass instructions and/or pointers to data to be copied.

The format, processing, and field definition of the CCB and BD are defined and performed entirely by the software script rather than the SDMA hardware. An overview of the format and structure is provided here, but for complete details refer to the SDMA software documentation (see [SDMA Scripts](#)).

The CCB and BD data structures are accessed by SDMA using DMA and processed by the SDMA scripts. The ROM contains common sub-routines for processing these data structures which may be called by the bootload and channel scripts.

**Figure 41-16. Data Structures Layout**

The previous figure shows an example how these data structures are linked to pass command and pointers to data buffers. The SDMA's MC0PTR register holds the base address of the Channel 0 Control Block (CCB0). The Channel 0 control block holds a pointer to the array of buffer descriptors. The buffer descriptors are used to tell the channel 0 (boot channel) what to do as described [Buffer Descriptor Format](#).

### 41.7.1.1 Buffer Descriptor Format

Buffer descriptors are three longs (32-bit words) in size as, shown in the figure found [here](#).

A buffer descriptor describes the properties of the data buffer it points to. The buffer descriptors can be used for linear or circular data buffers in the ARM platform processor memory. The CCB contains a pointer to the base BD as well as the current BD.

**Table 41-48. Buffer Descriptor**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Command								-	-	L	R	I	C	W	D	Count																
Buffer Address																																
Extended Buffer Address																																

**Table 41-49. Buffer Descriptor Field Descriptions**

Field	Description
31-24 Command	Command. The command field is used to differentiate operations performed within a script when the script accesses this particular buffer descriptor. The use of this field can be defined by the script. The command values defined for the bootstrap script are defined in <a href="#">Buffer Descriptor Commands for Bootstrap scripts</a> . Refer to the individual script definition in script library documents in <a href="#">SDMA Scripts</a> for command field definitions for other scripts.
23	Reserved
22	Reserved
21 L	Last Buffer Descriptor: This bit is set in SDMA IPC scripts to indicate to the receiving Core that the transfer has ended. Whenever the source finishes transferring the count it wanted to transfer, it sets LAST_BIT in the destination BD, to let the destination know that transfer is over. This bit also tells the destination software that when it processes the destination BDs, they need not process any BD after the BD with the LAST_BIT set. For example, when the DSP prepares a single buffer descriptor with count equals to 25 and ARM platform prepares a single buffer descriptor with count equals 100. When 25 bytes have been transferred from DSP to ARM platform, the DSP buffer descriptor is normally closed while the ARM platform buffer descriptor will have the L bit set and the byte count updated to 25.
20 R	erroR. Indicates an error occurred on the channel's buffer descriptor requested command. Some scripts may overwrite the command field with an error code indicating the source of the error. 0 No Error 1 Error
19 I	Interrupt. When SDMA has finished to process data transfer attached to this buffer descriptor, send an interrupt to the ARM platform. 0 No Interrupt 1 Interrupt the processor when BD is complete
18 C	CONTinuous. This buffer is allowed to receive multiple transmit buffers or is allowed to transmit to multiple receive buffers. The Continuous bit is decoded at the end of the processing of a BD to determine if the SDMA script must open a new BD to potentially continue the data transfer. 0 No further buffer descriptors 1 SDMA should move to the next Buffer descriptor after this one
17 W	Wrap. Indicates if this buffer descriptor is the last one for the channel control block. When encountering this bit set, the SDMA scripts updates the CurrentBD pointer to point to the first Buffer Descriptor of the array. This bit is set if the ARM platform wants to organize the array of BD in a circular way (like a ring). When all BD have been processed and if Wrap bit and CONTinuous bit are set in the last BD, the SDMA script will wrap around and it will try to re-open the first BD. 0 No Error 1 Wrap to first buffer descriptor after this one is processed.
16 D	D - "Done": bit 16: indicates the "ownership" of the buffer descriptor. When D=0 the host owns the buffer descriptor; when D=1 SDMA owns the buffer descriptor. In the case of the channel 0, D=1 indicates the SDMA has not yet processed this buffer, D=0 indicates the SDMA has processed this buffer. 0 ARM platform owns the buffer. 1 SDMA owns the buffer
15-0 Count	Count. the count field (bit 15-0) indicates the size of the data to be transmitted, the size of the data buffer pointed to by the buffer descriptor. The SDMA memory structure is different for program memory (16-bits shorts/half-words) and data memory (32-bits long). For channel 0 buffer descriptors, Count is expressed in 16-bit half-words when PM is addressed and in 32-bit words when DM is addressed. Count is typically expressed in bytes for other channel scripts, but the unit is dependant on the script.
31-0	Buffer address. Address pointer to the data buffer.
31-0	Extended buffer address. Additional pointer or other information required by some scripts.

The buffer descriptors form an array of programmable size. If the last buffer descriptor is marked by the Wrap flag-bit  $W=1$ , the array of buffer descriptor is treated as a ring with some logically continuous portion owned by the ARM platform with  $D=0$ , and the remainder owned by the SDMA with  $D=1$ . The count field of the buffer descriptor indicates how much data has been transmitted.

If ARM platform has prepared 3 buffers to be filled by the SDMA script, it has also prepared 3 BD, one for each buffer. The *Cont* and *Wrap* bits are used to organize the buffers in a circular way. For example, *CONTInous* bit is set to 1 in the 2 first BDs and *Wrap* is set in the 3<sup>rd</sup> BD. The SDMA script opens and processes BD#1. Since *CONTInous* bit is set for this BD, the SDMA will open the second BD and it will process it. Each time a BD is processed, its *Done* bit is reset by the SDMA. After the 3<sup>rd</sup> BD, if *CONTInous* is not set but if *Wrap* is set, the SDMA script stops here and the next time the channel will be triggered, the script will open the BD pointed by the currentBDptr pointer of the CCB and it will correspond to the first buffer descriptor.

If the *CONTInous* bit and *Wrap* bits are both set in the 3<sup>rd</sup> BD, the script will close it and it will try to open the first BD. An error may occur at this point if the BD#1 has already been processed and its *Done* bit is 0. The SDMA script cannot process a BD with a *Done* bit to 0. It means the BD is not ready to be processed. To avoid this situation, the *CONTInous* bit should not be set for the last BD if *Wrap* is set, and the Interrupt flag must set for the last BD. It will warn the owner of the BD that all the BDs have been processed and it has to re-set to 1 the *Done* bit of all the BD's if it desires the SDMA to fill them again. Basically, if the ARM platform expects the SDMA to fill up the buffers in a circular fashion, then it's the responsibility of the ARM platform to set the *Done* bit of a buffer descriptor at an appropriate time.

**Figure 41-17. Buffer Descriptor Flow**

The previous figure shows an example buffer descriptor flow. When the incoming data is stored and fills the first buffer of 25 bytes, the SDMA script opens the second BD because the CONTinuous bit was set. Then next incoming data is put in the second buffer. After receiving 50 bytes, the second buffer descriptor is also closed. The Done bit is reset and the third BD is opened. After receiving another 25 bytes, the third buffer is full and an interrupt is sent to the ARM platform because the Interrupt flag is set in the 3rd BD. The CONTinuous flag is not present the transfer is over. The next time the script will be triggered, the BD to be opened will be the first buffer descriptor since the Wrap flag was set in the 3rd BD. It is the ARM platform responsibility to set the Done bit of all the BD if it wants to use the same buffers.

### 41.7.1.2 Buffer Descriptor Commands for Bootload scripts

The command field of the buffer descriptor is defined separately for each script.

The following table lists the buffer descriptor commands defined for the channel 0 bootload script.

**Table 41-50. Channel Zero Buffer Descriptor Commands**

Command Field (binary)	Command	Description	Buffer Address	Extended Buffer Address
0000_0001 (0x01)	C0_SET_DM	Load SDMA data memory (RAM) from ARM platform memory buffer	ARM platform memory source address	SDMA memory destination address
0000_0010 (0x02)	C0_GET_DM	Copy SDMA data memory (RAM) to ARM platform memory buffer	ARM platform memory destination address	SDMA memory source address
0000_0100 (0x04)	C0_SET_PM	Load SDMA program memory (RAM) from ARM platform memory buffer	ARM platform memory source address	SDMA memory destination address
0000_0110 (0x06)	C0_GET_PM	Copy SDMA program memory (RAM) to ARM platform memory buffer	ARM platform memory destination address	SDMA memory source address
cccc_c111 (0x07   CHN)	C0_SETCTX	Load Context for channel cccc into SDMA RAM from ARM platform memory buffer	ARM Platform memory source address	-
cccc_c011 (0x03   CHN)	C0_GETCTXT	Copy Context for channel ccccc from SDMA RAM to ARM platform memory buffer	ARM platform memory destination address	-

The Channel 0 bootload commands are summarized as follows:

- **C0\_SET\_[PM-DM]:** load the buffer descriptor data in the SDMA local memory at the address pointed to by the "extended buffer address" field. The SDMA RAM can be seen as a Program Memory (PM, 16-bit address) or Data Memory (DM 32-bit address). When C0\_SET\_PM is used, the count field is expressed in "shorts" (16-bit

half words), this command can be used to download scripts. When C0\_SET\_DM is used, the count field is expressed in "long" (32-bit words), this command can be used to download channel contexts to the context channel area in RAM.

- C0\_GET\_[PM-DM]: write to the buffer descriptor's data buffer the content of the SDMA local memory from the address pointed to by the "extended buffer address" field for the length defined by the count in the buffer descriptor. C0\_GET\_PM is used to dump some part of the Program Memory (may be used to dump context of a channel), therefore count is expressed in "shorts"; while C0\_GET\_DM is used to dump to the buffer descriptor's data buffer, so the count field is in "longs."
- C0\_SETCTX: load a context into the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using the channel number the script computes the offset of the context data pointer for the channel relative to the context page base to use as the destination address in SDMA memory. Then the C0\_SET\_DM command explained above is invoked to load SDMA RAM from memory. The counter indicates the size in words of the context structure.
- Command value: (in binary) cccc c111, where ccccc is the channel number (5 bits). For instance, 0x0F means set context for channel 1, 0xFF means set context for channel 31.
- C0\_GETCTX: write to the buffer descriptor's data buffer the content of the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using this channel number, the script computes the offset of the context data pointer for the channel relative to the context page base to use as the source address for the copy. Then the C0\_GET\_DM command explained above is invoked to copy the context to memory. The counter indicates the size in words of the context structure.
- Command value: (in binary): cccc c011, where ccccc is the channel number (5 bits). For instance, 0x03 means get context of channel 1, 0xFB means get context of channel 31.

### NOTE

To download channel context, C0\_SETDM and C0\_SETCTXT command can be used but the second one is easier because the channel number is embedded into the command field, whereas with the C0\_SETDM, the pointer to the channel context area must be written into the extended buffer address field of the buffer descriptor.

### 41.7.1.3 Example of Buffer Descriptors for Channel 0.

Figure 41-19 illustrates the buffer descriptors that must be set in ARM platform memory space, before execution of boot code, to download contexts and scripts of channels 1, 4, and 10. After boot code execution, SDMA memory will be populated with the different contexts and scripts as presented in the following figure.

#### 41.7.1.4 Channel Context

There are 32 channel context memory structures pointed to by the local save area pointer. These channel context memory structures are fixed.

The script in the SDMA computes the memory offset for a given channel based on the structure length and channel number. Figure below shows the structure of the channel context as it is saved in the SDMA local memory (RAM).

A channel context consists in 24 words, one per register. A total of 32 words are reserved for every channel. The additional 8 words are called scratch ram and they are dedicated to each channel. This memory area is commonly used for stack management.

The structure is divided in 4 areas:

- Channel status registers
- General purpose registers
- Functional units state registers reflecting the state of the ARM platform DMAs (Burst and Peripheral DMA).
- Scratch RAM

The details of the channel context status registers are described in the following figure.

The PC field of the first long register must point to the SDMA RAM address where the script that will be executed on the channel is located and this value equals the one stored in the extended buffer address of the buffer descriptor with C0\_SETPM command.

31	30	29	16	15	14	13	0

## 41.7.2 Typical Data Transfer Supported by SDMA DMA Units

This section presents a library of SDMA scripts that perform data transfers through the peripheral DMA and the burst DMA units.

The ARM platform memory and peripherals are devices that either the peripheral DMA or the burst DMA can access. The scripts are given for a peripheral DMA whose address registers are programmed in incremented mode when internal memory is involved. See the following table for the summary.

**Table 41-51. Typical Data Transfers Summary**

Data Transfer	Peripheral DMA	Burst DMA	Comments
ARM platform External Memory ↔ ARM platform External Memory		3	Copy mode Script example, see <a href="#">Burst DMA Unit Copy Mode</a> and <a href="#">External Memory to External Memory</a> .
ARM platform Peripheral ↔ ARM platform Peripheral	3		Copy mode if same data path width Script example, see <a href="#">Peripheral to Peripheral Transfer</a> .
ARM platform External Memory ↔ ARM platform Peripheral	3	3	Data transit through SDMA Script example, see <a href="#">Transfer Between Peripheral and External Memory</a> .
ARM platform External Memory ↔ ARM platform Internal Memory		3	Copy mode Script example, see <a href="#">Transfer Between External Memory and Internal Memory</a> .
ARM platform Internal Memory ↔ ARM platform Internal Memory		3	Copy mode Script example, see <a href="#">Internal Memory to Internal Memory</a> .
ARM platform Internal memory ↔ ARM platform Peripheral	3		Data transit through SDMA Script example, see <a href="#">Transfer Between Peripheral and Internal Memory</a> .

### NOTE

These scripts are provided as examples of how to use DMA blocks to perform required data transfers: They are not "official" programs.

### 41.7.2.1 External Memory to External Memory

This section describes the SDMA script that performs data moves in external memory.

For this particular data transfer, only the burst DMA is used. It is programmed in copy mode, so no data transmits through an SDMA general register.

The SDMA core only monitors data transfer status. It is assumed source and destination address values are already present in two SDMA general registers (r1 and r2). For this example, it is also assumed that a 32-bit word-to-move for source-to-destination address is present in r0 and equals 64.

### Data Moves in External Memory

```

1      stf r1,MSA                      // Source address setup
2      stf r2,MDA                      // Destination address setup
3      ldi r0,0x64                     // 64 words must be transferred from MSA to
MDA
4      ldi r1,0x8
MAIN_XFER:
5      cmpbs r0,r1                    // Is r0 >= 0x8
6      bf LAST_XFER                   // If not, jump to last transfer label
7      stf r1,MD|CPY                  // Copy 8 words from MSA to MDA address.
8      subi r0,0x8                    // Decrement counter
9      jmp MAIN_XFER                  // return to main transfer loop
LAST_XFER:
10     stf r0,MD|CPY                  // perform last transfer

```

All instructions are performed in one cycle (jumps excepted). Instruction 7 triggers a copy transfer: A read burst access of 8-word starts, data is staged in MD and then a write burst of 8 words is executed. Instruction 8, 9, 5, and 6 are executed while the burst access is in progress. If this access is not complete when instruction 7 is executed a second time, SDMA stalls on this instruction as long as the previous copy transfer is not over. In this case, the instruction is no longer a one-cycle instruction.

During the main loop (MAIN\_XFER), r1 always equals 8, so burst lengths are 8 words. On the last ldf |CPY instruction (10), r1 equals the remainder of r0 divided by 8; therefore, the length of bursts triggered in copy mode equal r1 value, which is between 1 and 7.

### 41.7.2.2 Peripheral to Peripheral Transfer

For this data transfer, only the peripheral DMA is used.

It is programmed in copy mode, so no data will transmit through the SDMA general register used in the ldf instruction, but the contents of the general register are lost. The SDMA core only monitors the transfer.

### 41.7.2.2.1 Source and Destination Target Have the Same Data Path Width

When the source and destination target have the same data path width, the following is true:

- Source target is a *half-word* (16-bit) peripheral located at address 0x1002.
- Destination is a *half-word* (16-bit) peripheral located at address 0x2006.

It is assumed the address values are already present in two SDMA general registers (r1, r2). The script for a transfer of 10 half-word is as follows:

#### Same Data Path Width for Source and Destination

```
//SETUP SECTION
1      stf r1, PSA|SZ16|F           //r1=0x1002 Source address register setup
2      stf r2, PDA|SZ16|F           //r2=0x2006 Destination address register
setup
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0xa                   //loop counter is 10
//MAIN LOOP TRANSFER
copy_loop:

5      loop 2,0
6      ldf r7,PD|CPY                //Reads 1 half-word from src and writes to
dest.
7      yield
8      bdf ERROR_DURING_XFER
ERROR_ADDR_SETUP:                  //correction of PSA/PDA setup and jumps to main loop transfer
ERROR_DURING_XFER:
//flag error is set,
//PS can be read to know if error occurs during read or write access.
```

If a data transfer must occur between two word peripherals, only the setup section should be updated. The transfer itself is always performed by the hardware loop instruction.

All instructions are executed in one cycle (change of flow excepted). On instruction 6, a single read access is triggered, read data is staged in PD, and a write-to-destination is executed. When the transfers are in progress, the SDMA can execute the next instructions in parallel. If instruction 6, which performs the copy transfer, is executed while the previous access is not over, SDMA is stalled and instruction ldf is a multi-cycle instruction.

### 41.7.2.2.2 Source and Destination Target Have a Different Data Path Width

When the source and destination target have a different data path width, copy mode cannot be used, and any attempt to initiate a copy transfer immediately raises an error, which is stored in the SF flag.

The following example shows the SDMA code that could transfer 10 words from a *word* (32-bit) peripheral to a *half-word* peripheral whose addresses are preliminary and stored in r1 and r2.

## Different Data Path Width for Source and Destination

```
//SETUP SECTION
1      stf r1, PSA|SZ32|F|PF          //r1=0x1000 and prefetch data
2      stf r2, PDA|SZ16|F            //r2=0x2006
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0xa                     //loop counter is 10
//MAIN LOOP TRANSFER
main_loop_xfer_16_16:
5      loop 6,0
6      ldf r7,PD                      //copy 32-bit of PD in r7
7      stf r7,PD                      //store 16 LSB of r7 in PD and a flush is
executed
8      rorb r7
9      rorb r7                        //16 MSB --> 16 LSB
10     stf r7,PD                      //store 16 LSB of r6 in PD and a flush.
11     yield
```

On instruction 1, when the source address register is programmed and a data prefetch is required, a read access is executed. In parallel, the SDMA executes instructions 2 to 5. On instruction 6, the SDMA tries to read data that was fetched by instruction 1. If data is ready, the ldf will be a one cycle instruction; otherwise, the SDMA is stalled as long as the read access is not finished. Then, the 16 LSB of the read data is stored in PD and automatically flushed to the destination peripheral. In parallel, the SDMA executes the rotation instructions (8, 9), and stores the 16 MSB of the read data into PD. If a previous write access is finished, instruction 10 will be a one-cycle instruction.

The main loop transfer may appear inefficient, but due to wait states imposed to the peripheral DMA each time an external access is performed, a software pipeline is in place. During the time needed to flush PD, the SDMA executes the move and rotation operations. SDMA executes instructions in parallel with DMA accesses.

### 41.7.2.3 Transfer Between Peripheral and External Memory

#### 41.7.2.3.1 Peripheral to External Memory Transfer

A transfer from a peripheral to the external memory controller involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from word peripheral to the external memory would be as follows:

#### Peripheral to External Memory Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1      stf r1, PSA|SZ16|F|PF          //r1=0x1000 and prefetch 32-bit data
2      stf r2, MDA                    //r2=0x2000, setup burst DMA destination
address
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0x64                     //loop counter is 100
5
//MAIN LOOP TRANSFER
6      loop 3,0
```

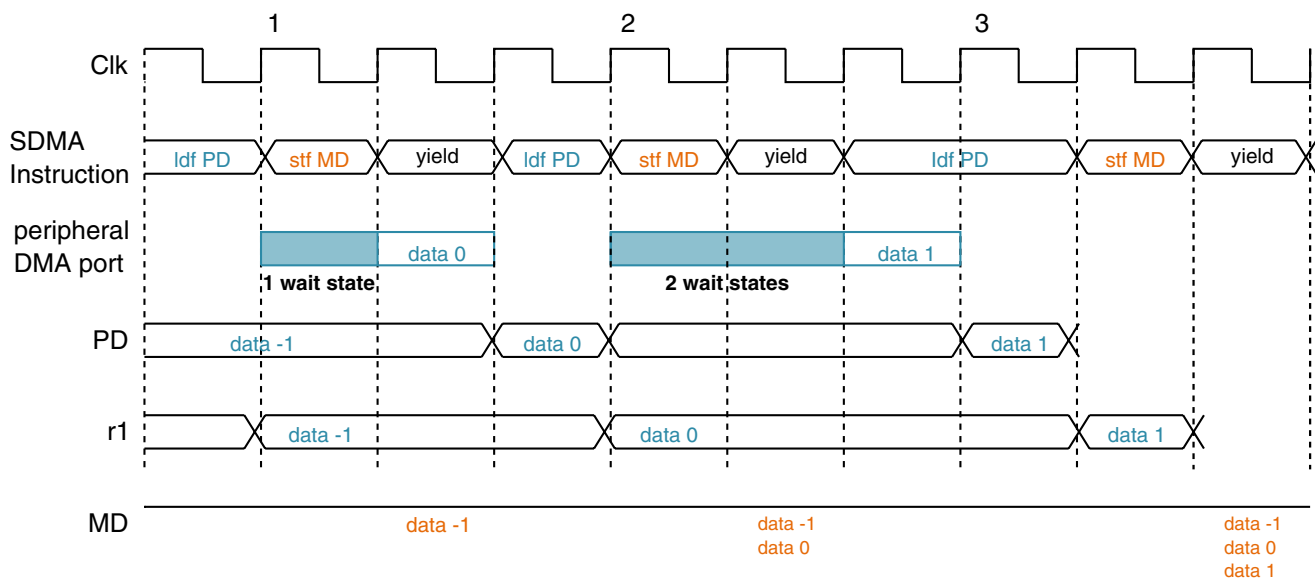

## Application Notes

```

7          ldf r1,PD|PF          // read 32 bits of PD and initiate a new read
access.
8          stf r1,MD|32          // store 32 bits of r1 in the MD fifo.
9          yield
10         ldf r1,PD             // last word data is read
11         stf r1,MD|32|FL       // to flush all remaining bytes of MD

```

On instruction 1, the source address register of the peripheral DMA is programmed and data is fetched. This data is stored in PD and the SDMA reads PD during instruction 7, which is a one-cycle instruction that is read-access finished. On the same instruction (7), a data prefetch is required and a read access to the source peripheral is executed. In parallel, the SDMA stored the previous read data into the data register of MD. When MD (which is an eight-word FIFO) is full, a burst write access is executed to empty the FIFO. As long as the next SDMA instructions do not access the burst DMA, they will be one-cycle instructions. The following figures show how the peripheral DMA and burst DMA work in parallel.

**Figure 41-21. Peripheral to External Memory Example (1)**

As seen in the figure above, the read access triggered by the `ldf PD` instruction is symbolized by the blue bar when in progress. After wait states, the read data (data 0, data 1) is stored in PD on the clk rising edge. On edge 2, data 0 is available in PD so it can be transferred to the SDMA general register r1, and then stored in MD FIFO. On edge 3, data 1 is not in PD; therefore, SDMA is stalled on the `ldf` instruction, which lasts two cycles. The figure below shows an example of when MD FIFO is full with data.

**Figure 41-22. Peripheral to External Memory Example (2)**

In the previous figure, the write bar means the burst DMA is performing a write burst access. The latency to have the first write acknowledge is four cycles. SDMA is stalled on instruction `stf` because no acknowledge was received, MD FIFO is full, and there is no empty slot to store `data 9`. When an acknowledge is sampled by the burst DMA, FIFO is shifted and `data 8` is written. As long as there is at least one empty slot in MD FIFO, the `stf MD` instruction lasts one cycle.

#### 41.7.2.3.2 External Memory to Peripheral Transfer

A transfer from the external memory to a peripheral involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from external memory to a word peripheral would be as follows:

##### External Memory to Peripheral Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1      stf r1, MSA|PF           //r1=0x1000 and starts a 8-word read burst
2      stf r2, PDA|SZ32|P       //r2=0x2010, setup peripheral DMA destination address
3      bdf ERROR_ADDR_SETUP
4      ldi r0,0x64              //loop counter is 100
//MAIN LOOP TRANSFER
6      loop 3,0
```

```

7      ldf r1,MD|32|PF          // read 32 bits of MD and initiate a new read access
                                   // if MD is empty after this reading.
8      stf r1,PD                // store 32 bits of r1 in the PD.
9      yield
10     ldf r1,MD|32             // last word data is read
11     stf r1,PD                // last write access

```

On instruction 1, a read burst of 8 words begins. Read data is staged into MD. On instruction 7 (and if data is available in MD), 32 bits are copied into r1. Then instruction 8 writes them into PD and an automatic flush is executed. The SDMA core, peripheral DMA, and burst DMA can work in parallel as long as no SDMA instruction tries to start a new write access on the peripheral DMA while the previous access is still in progress, or as long as there is data in MD when the SDMA tries to read it.

#### 41.7.2.4 Transfer Between External Memory and Internal Memory

Since the internal memory (ARM platform RAM) is accessed via the peripheral DMA and the external memory is accessed via the burst DMA, the SDMA scripts that are described in [Transfer Between Peripheral and External Memory](#) can be reused. The exception is that the peripheral DMA address registers (PSA or PDA, depending on the script) should be programmed in incremented mode rather than frozen mode.

##### 41.7.2.4.1 Internal Memory to Internal Memory

The internal memory can only be accessed via the peripheral DMA, so the script described in [Peripheral to Peripheral Transfer](#) can be reused with a different programming of the peripheral DMA address registers.

##### 41.7.2.4.2 Transfer Between Peripheral and Internal Memory

For this transfer, the peripheral DMA is also used in copy mode.

The SDMA script is very similar to the one described in [Peripheral to Peripheral Transfer](#), except for the peripheral DMA address registers programming.

## 41.8 ARM Platform Memory Map and Control Register Definitions

The ARM platform controls the SDMA by means of several interface registers. Those registers are described in the current section.

All registers are clocked with the SDMA clock (which means the ARM platform must ensure that the SDMA clock is running when it wants to access any register).

### SDMAARM\_MC0PTR field descriptions

Field	Description
31–0 MC0PTR	<b>Channel 0 Pointer</b> contains the 32-bit address, in ARM platform memory, of channel 0 control block (the boot channel). Appendix A fully describes the SDMA Application Programming Interface (API). The ARM platform has a read/write access and the SDMA has a read-only access.

## 41.8.2 Channel Interrupts (SDMAARM\_INTR)

Address: 20E\_C000h base + 4h offset = 20E\_C004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### SDMAARM\_INTR field descriptions

Field	Description
31–0 HI[31:0]	The ARM platform Interrupts register contains the 32 HI[i] bits. If any bit is set, it will cause an interrupt to the ARM platform. This register is a "write-ones" register to the ARM platform. When the ARM platform sets a bit in this register the corresponding HI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced, failure to do so will cause continuous interrupts. The SDMA is responsible for setting the HI[i] bit corresponding to the current channel when the corresponding <code>done</code> instruction is executed.

## 41.8.3 Channel Stop/Channel Status (SDMAARM\_STOP\_STAT)

Address: 20E\_C000h base + 8h offset = 20E\_C008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HE																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**SDMAARM\_STOP\_STAT field descriptions**

Field	Description
31–0 HE	This 32-bit register gives access to the ARM platform Enable bits. There is one bit for every channel. This register is a "write-ones" register to the ARM platform. When the ARM platform writes 1 in bit <i>i</i> of this register, it clears the HE[ <i>i</i> ] and HSTART[ <i>i</i> ] bits. Reading this register yields the current state of the HE[ <i>i</i> ] bits.

**41.8.4 Channel Start (SDMAARM\_HSTART)**

Address: 20E\_C000h base + Ch offset = 20E\_C00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HSTART_HE																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**SDMAARM\_HSTART field descriptions**

Field	Description
31–0 HSTART_HE	<p>The HSTART_HE registers are 32 bits wide with one bit for every channel. When a bit is written to 1, it enables the corresponding channel. Two physical registers are accessed with that address (HSTART and HE), which enables the ARM platform to trigger a channel a second time before the first trigger is processed.</p> <ul style="list-style-type: none"> <li>This register is a "write-ones" register to the ARM platform. Neither HSTART[<i>i</i>] bit can be set while the corresponding HE[<i>i</i>] bit is cleared.</li> <li>When the ARM platform tries to set the HSTART[<i>i</i>] bit by writing a one (if the corresponding HE[<i>i</i>] bit is clear), the bit in the HSTART[<i>i</i>] register will remain cleared and the HE[<i>i</i>] bit will be set.</li> <li>If the corresponding HE[<i>i</i>] bit was already set, the HSTART[<i>i</i>] bit will be set. The next time the SDMA channel <i>i</i> attempts to clear the HE[<i>i</i>] bit by means of a <code>done</code> instruction, the bit in the HSTART[<i>i</i>] register will be cleared and the HE[<i>i</i>] bit will take the old value of the HSTART[<i>i</i>] bit.</li> <li>Reading this register yields the current state of the HSTART[<i>i</i>] bits. This mechanism enables the ARM platform to pipeline two HSTART commands per channel.</li> </ul>

**41.8.5 Channel Event Override (SDMAARM\_EVTOVR)**

Address: 20E\_C000h base + 10h offset = 20E\_C010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**SDMAARM\_EVTOVR field descriptions**

Field	Description
31–0 EO	The Channel Event Override register contains the 32 EO[ <i>i</i> ] bits. A bit set in this register causes the SDMA to ignore DMA requests when scheduling the corresponding channel.

## 41.8.6 Channel BP Override (SDMAARM\_DSPOVR)

Address: 20E\_C000h base + 14h offset = 20E\_C014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### SDMAARM\_DSPOVR field descriptions

Field	Description
31–0 DO	This register is reserved. All DO bits should be set to the reset value of 1. A setting of 0 will prevent SDMA channels from starting according to the condition described in <a href="#">Runnable Channels Evaluation</a> .  0 - Reserved 1 - Reset value.

## 41.8.7 Channel ARM platform Override (SDMAARM\_HOSTOVR)

Address: 20E\_C000h base + 18h offset = 20E\_C018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### SDMAARM\_HOSTOVR field descriptions

Field	Description
31–0 HO	The Channel ARM platform Override register contains the 32 HO[i] bits. A bit set in this register causes the SDMA to ignore the ARM platform enable bit (HE) when scheduling the corresponding channel.

## 41.8.8 Channel Event Pending (SDMAARM\_EVTPEND)

Address: 20E\_C000h base + 1Ch offset = 20E\_C01Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**SDMAARM\_EVTPEND field descriptions**

Field	Description
31–0 EP	<p>The Channel Event Pending register contains the 32 EP[i] bits. Reading this register enables the ARM platform to determine what channels are pending after the reception of a DMA request.</p> <ul style="list-style-type: none"> <li>Setting a bit in this register causes the SDMA to reevaluate scheduling as if a DMA request mapped on this channel had occurred. This is useful for starting up channels, so that initialization is done before awaiting the first request. The scheduler can also set bits in the EVTPEND register according to the received DMA requests.</li> <li>The EP[i] bit may be cleared by the <code>done</code> instruction when running the channel <i>i</i> script. This is a "write-ones" mechanism: Writing a '0' does not clear the corresponding bit.</li> </ul>

**41.8.9 Reset Register (SDMAARM\_RESET)**

Address: 20E\_C000h base + 24h offset = 20E\_C024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0												RESCHED		RESET	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**SDMAARM\_RESET field descriptions**

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

**SDMAARM\_RESET field descriptions (continued)**

Field	Description
1 RESCHED	When set, this bit forces the SDMA to reschedule as if a script had executed a <code>done</code> instruction. This enables the ARM platform to recover from a runaway script on a channel by clearing its HE[i] bit via the STOP register, and then forcing a reschedule via the RESCHED bit. The RESCHED bit is cleared when the context switch starts.
0 RESET	When set, this bit causes the SDMA to be held in a software reset. The internal reset signal is held low 16 cycles; the RESET bit is automatically cleared when the internal reset signal rises.

**41.8.10 DMA Request Error Register (SDMAARM\_EVTERR)**

Address: 20E\_C000h base + 28h offset = 20E\_C028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**SDMAARM\_EVTERR field descriptions**

Field	Description
31–0 CHNERR	<p>This register is used by the SDMA to warn the ARM platform when an incoming DMA request was detected and it triggers a channel that is already pending or being serviced. This probably means there is an overflow of data for that channel.</p> <ul style="list-style-type: none"> <li>An interrupt is sent to the ARM platform if the corresponding channel bit is set in the INTRMASK register.</li> <li>This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the ARM platform or during SDMA reset.</li> <li>The CHNERR[i] bit is set when a DMA request that triggers channel <i>i</i> is received through the corresponding input pins and the EP[i] bit is already set; the EVTERR[i] bit is unaffected if the ARM platform tries to set the EP[i] bit, whereas, that EP[i] bit is already set.</li> </ul>

**41.8.11 Channel ARM platform Interrupt Mask (SDMAARM\_INTRMASK)**

Address: 20E\_C000h base + 2Ch offset = 20E\_C02Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**SDMAARM\_PSW field descriptions**

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–13 NCP[2:0]	The Next Channel Priority gives the next pending channel priority. When the priority is 0, it means there is no pending channel and the NCR value has no meaning.  0 No running channel 1 Active channel priority
12–8 NCR[4:0]	The Next Channel Register indicates the number of the next scheduled pending channel with the highest priority.
7–4 CCP[2:0]	The Current Channel Priority indicates the priority of the current active channel. When the priority is 0, no channel is running: The SDMA is idle and the CCR value has no meaning. In the case that the SDMA has finished running the channel and has entered sleep state, CCP will indicate the priority of previous running channel.  0 No running channel 1 Active channel priority
3–0 CCR[4:0]	The Current Channel Register indicates the number of the channel that is being executed by the SDMA. SDMA. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel.

**41.8.13 DMA Request Error Register (SDMAARM\_EVTERRDBG)**

Address: 20E\_C000h base + 34h offset = 20E\_C034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	

**SDMAARM\_CONFIG field descriptions**

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 DSPDMA	This bit's function is reserved and should be configured as zero. 0 - Reset Value 1 - Reserved
11 RTDOBS	Indicates if Real-Time Debug pins are used: They do not toggle by default in order to reduce power consumption. 0 RTD pins disabled 1 RTD pins enabled
10–5 Reserved	This read-only field is reserved and always has the value 0.
4 ACR	ARM platform DMA / SDMA Core Clock Ratio. Selects the clock ratio between ARM platform DMA interfaces (burst DMA and peripheral DMA) and the internal SDMA core clock. The frequency selection is determined separately by the chip clock controller. This bit has to match the configuration of the chip clock controller that generates the clocks used in the SDMA. 0 ARM platform DMA interface frequency equals twice core frequency 1 ARM platform DMA interface frequency equals core frequency
3–2 Reserved	This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

**SDMAARM\_CONFIG field descriptions (continued)**

Field	Description
1–0 CSM	<p>Selects the Context Switch Mode. The ARM platform has a read/write access. The SDMA cannot modify that register. The value at reset is 3, which selects the dynamic context switch by default. That register can be modified at anytime but the new context switch configuration will only be taken into account at the start of the next restore phase.</p> <p>NOTE: The first call to SDMA's channel 0 Bootload script after reset should use static context switch mode to ensure the context RAM for channel 0 is initialized in the channel SAVE Phase. After Channel 0 is run once, then any of the dynamic context modes can be used.</p> <p>0 static 1 dynamic low power 2 dynamic with no loop 3 dynamic</p>

**41.8.15 SDMA LOCK (SDMAARM\_SDMA\_LOCK)**

Address: 20E\_C000h base + 3Ch offset = 20E\_C03Ch

W																
Reset	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0

**SDMAARM\_ONCE\_STAT field descriptions**

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 PST[3:0]	<p>The Processor Status bits reflect the state of the SDMA RISC engine. Its states are as follows:</p> <ul style="list-style-type: none"> <li>• The "Program" state is the usual instruction execution cycle.</li> <li>• The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st).</li> <li>• The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions).</li> <li>• The "Change of Flow in Loop" state is used when an error causes a hardware loop exit.</li> <li>• The "Debug" state means the SDMA is in debug mode.</li> <li>• The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf).</li> <li>• In "Sleep" modes, no script is running (this is the RISC engine idle state). The "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 will be executed (boot operation).</li> <li>• The "in Sleep" states are the same as above except they do not have any corresponding channel: They are used when entering debug mode after reset. The reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode.</li> </ul> <p>0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Save 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Restore</p>
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an <code>rbuffer</code> command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	<p>This flag is raised when the OnCE is controlled from the ARM platform peripheral interface.</p> <p>0 The JTAG interface controls the OnCE. 1 The ARM platform peripheral interface controls the OnCE.</p>
6–3 Reserved	This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

**SDMAARM\_ONCE\_STAT field descriptions (continued)**

Field	Description
2–0 ECDR	<p>Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one of the EDR bits is set (the meaning of the encoding is given below). The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addra_cond, addrb_cond, and data_cond conditions. The value of those fields is given by the EDR bits.</p> <p>0 1 matched addra_cond  1 1 matched addrb_cond  2 1 matched data_cond</p>

**41.8.20 OnCE Command Register (SDMAARM\_ONCE\_CMD)**

Address: 20E\_C000h base + 50h offset = 20E\_C050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**SDMAARM\_ONCE\_CMD field descriptions**

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value 0.
3–0 CMD	<p>Writing to this register will cause the OnCE to execute the command that is written. When needed, the ONCE_DATA and ONCE_INSTR registers should be loaded with the correct value before writing the command to that register. For a list of the OnCE commands and their usage, see <a href="#">OnCE and Real-Time Debug</a>.</p> <p><b>NOTE:</b> 7-15 reserved</p> <p>0 rstatus  1 dmov  2 exec_once  3 run_core  4 exec_core  5 debug_rqst  6 rbuffer</p>

### 41.8.21 Illegal Instruction Trap Address (SDMAARM\_ILLINSTADDR)

Address: 20E\_C000h base + 58h offset = 20E\_C058h

SDMAARM\_ILLINSTADDR field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13–0 ILLINSTADDR	The Illegal Instruction Trap Address is the address where the SDMA jumps when an illegal instruction is executed. It is 0x0001 after reset.  The value of ILLINSTADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.

### 41.8.22 Channel 0 Boot Address (SDMAARM\_CHN0ADDR)

Address: 20E\_C000h base + 5Ch offset = 20E\_C05Ch

SDMAARM\_CHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value 0.
14 SMSZ	The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context,

Table continues on the next page...

**SDMAARM\_CHN0ADDR field descriptions (continued)**

Field	Description
	<p>which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism.</p> <p>The value of SMSZ cannot be changed if the LOCK bit in the SDMA_LOCK register is set.</p> <p>0 24 words per context 1 32 words per context</p>
13–0 CHN0ADDR	<p>This 14-bit register is used by the boot code of the SDMA. After reset, it points to the standard boot routine in ROM (channel 0 routine). By changing this address, you can perform a boot sequence with your own routine. The very first instructions of the boot code fetch the contents of this register (it is also mapped in the SDMA memory space) and jump to the given address. The reset value is 0x0050 (decimal 80).</p> <p>The value of CHN0ADDR cannot be changed if the LOCK bit in the SDMA_LOCK register is set.</p>

**41.8.23 DMA Requests (SDMAARM\_EVT\_MIRROR)**

Address: 20E\_C000h base + 60h offset = 20E\_C060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**SDMAARM\_XTRIG\_CONF1 field descriptions**

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30 CNF3	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by the reception of a DMA request or by the starting of a channel script execution.  0 channel 1 DMA request
29–24 NUM3[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
23 Reserved	This read-only field is reserved and always has the value 0.

*Table continues on the next page...*

**SDMAARM\_XTRIG\_CONF1 field descriptions (continued)**

Field	Description
22 CNF2	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution.  0 channel 1 DMA request
21–16 NUM2[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
15 Reserved	This read-only field is reserved and always has the value 0.
14 CNF1	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution.  0 channel 1 DMA request
13–8 NUM1[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
7 Reserved	This read-only field is reserved and always has the value 0.
6 CNF0	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution.  0 channel 1 DMA request
5–0 NUM0[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .

## 41.8.26 Cross-Trigger Events Configuration Register 2 (SDMAARM\_XTRIG\_CONF2)

Address: 20E\_C000h base + 74h offset = 20E\_C074h

### SDMAARM\_XTRIG\_CONF2 field descriptions

Field	Description
31 Reserved	This read-only field is reserved and always has the value 0.
30 CNF7	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution.  0 channel 1 DMA request
29–24 NUM7[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
23 Reserved	This read-only field is reserved and always has the value 0.
22 CNF6	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution.  0 channel 1 DMA request
21–16 NUM6[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
15 Reserved	This read-only field is reserved and always has the value 0.
14 CNF5	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution

Table continues on the next page...

**SDMAARM\_XTRIG\_CONF2 field descriptions (continued)**

Field	Description
	0 channel 1 DMA request
13–8 NUM5[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .
7 Reserved	This read-only field is reserved and always has the value 0.
6 CNF4	Configuration of the SDMA event line number <i>i</i> that is connected to the cross-trigger. It determines whether the event line pulse is generated by receiving a DMA request or by starting a channel script execution.  0 channel 1 DMA request
5–0 NUM4[5:0]	Contains the number of the DMA request or channel that triggers the pulse on the cross-trigger event line number <i>i</i> .

**41.8.27 Channel Priority Registers (SDMAARM\_SDMA\_CHNPRIn)**

Address: 20E\_C000h base + 100h offset + (4d × *i*), where *i*=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																CHNPRIn															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**SDMAARM\_SDMA\_CHNPRIn field descriptions**

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
2–0 CHNPRIn	This contains the priority of channel number <i>n</i> . Useful values are between 1 and 7; 0 is reserved by the SDMA hardware to determine when there is no pending channel. Reset value is 0, which prevents the channels from starting.

**41.8.28 Channel Enable RAM (SDMAARM\_CHNENBLn)**

Address: 20E\_C000h base + 200h offset + (4d × *i*), where *i*=0d to 47d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARM\_CHNENBL $n$  field descriptions

Field	Description
31–0 ENBL $n$	This 32-bit value selects the channels that are triggered by the DMA request number $n$ . If ENBL $n$ [ $i$ ] is set to 1, bit EP[ $i$ ] will be set when the DMA request $n$ is received. These 48 32-bit registers are physically located in a RAM, with no known reset value. It is thus essential for the ARM platform to program them before any DMA request is triggered to the SDMA, otherwise an unpredictable combination of channels may be started.

## 41.9 BP Memory Map and Control Register Definitions

The following section describes SDMA control registers available to the BP.

### NOTE

These registers are physically implemented in all platforms, but are not accessible when the SDMA BP control port is not connected. Reset values are calculated to allow the system to work when those registers cannot be accessed.

All registers are clocked with the SDMA clock (which means the SDMA clock must be running when the BP wants to access any register).

### SDMABP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
20E_C000	Channel 0 Pointer (SDMABP_DC0PTR)	32	R/W	0000_0000h	<a href="#">41.9.1/2624</a>
20E_C004	Channel Interrupts (SDMABP_INTR)	32	w1c	0000_0000h	<a href="#">41.9.2/2625</a>
20E_C008	Channel Stop/Channel Status (SDMABP_STOP_STAT)	32	R/W	0000_0000h	<a href="#">41.9.3/2625</a>

**SDMABP\_DC0PTR field descriptions**

Field	Description
31–0 DC0PTR	<b>Channel 0 Pointer</b> contains the 32-bit address, in BP memory, of the array of channel control blocks starting with the one for channel 0 (the control channel). This register should be initialized by the BP before it enables a channel (for example, channel 0). See the API document SDMA Scripts User Manual for the use of this register. The BP has a read/write access and the SDMA has a read-only access.

**41.9.2 Channel Interrupts (SDMABP\_INTR)**

Address: 20E\_C000h base + 4h offset = 20E\_C004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**SDMABP\_INTR field descriptions**

Field	Description
31–0 DI	The BP Interrupts register contains the 32 DI[i] bits. If any bit is set, it will cause an interrupt to the BP. <ul style="list-style-type: none"> <li>This register is a "write-ones" register to the BP. When the BP sets a bit in this register, the corresponding DI[i] bit is cleared.</li> <li>The interrupt service routine should clear individual channel bits when their interrupts are serviced; failure to do so will cause continuous interrupts.</li> <li>The SDMA is responsible for setting the DI[i] bit corresponding to the current channel when the corresponding <code>done</code> instruction is executed.</li> </ul>

**41.9.3 Channel Stop/Channel Status (SDMABP\_STOP\_STAT)**

Address: 20E\_C000h base + 8h offset = 20E\_C008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**SDMABP\_STOP\_STAT field descriptions**

Field	Description
31–0 DE	This 32-bit register gives access to the BP (DSP) Enable bits, DE. There is one bit for every channel. <ul style="list-style-type: none"> <li>This register is a "write-ones" register to the BP.</li> <li>When the BP writes 1 in bit <i>i</i> of this register, it clears the DE[i] and DSTART[i] bits.</li> <li>Reading this register yields the current state of the DE[i] bits.</li> </ul>

## 41.9.4 Channel Start (SDMABP\_DSTART)

Address: 20E\_C000h base + Ch offset = 20E\_C00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### SDMABP\_DSTART field descriptions

Field	Description
31–0 DSTART_DE	<p>The DSTART_DE registers are 32 bits wide with one bit for every channel.</p> <ul style="list-style-type: none"> <li>When a bit is written to 1, it enables the corresponding channel.</li> <li>Two physical registers are accessed with that address (DSTART and DE), which enables the BP to trigger a channel a second time before the first trigger was processed.</li> <li>This register is a "write-ones" register to the BP. Neither DSTART[i] bit can be set while the corresponding DE[i] bit is cleared.</li> <li>When the BP tries to set the DSTART[i] bit by writing a one (if the corresponding DE[i] bit is clear), the bit in the DSTART[i] register will remain cleared and the DE[i] bit will be set. If the corresponding DE[i] bit was already set, the DSTART[i] bit will be set.</li> <li>The next time the SDMA channel <i>i</i> attempts to clear the DE[i] bit by means of a <code>done</code> instruction, the bit in the DSTART[i] register will be cleared and the DE[i] bit will take the old value of the DSTART[i] bit.</li> <li>Reading this register yields the current state of the DSTART[i] bits. This mechanism enables the BP to pipeline two DSTART commands per channel.</li> </ul>

## 41.9.5 DMA Request Error Register (SDMABP\_EVTERR)

Address: 20E\_C000h base + 28h offset = 20E\_C028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### SDMABP\_EVTERR field descriptions

Field	Description
31–0 CHNERR	<p>This register is used by the SDMA to warn the BP when an incoming DMA request was detected; it then triggers a channel that is already pending or being serviced, which may mean there is an overflow of data for that channel. An interrupt is sent to the BP if the corresponding channel bit is set in the INTRMASK register.</p> <ul style="list-style-type: none"> <li>This is a "write-ones" register for the scheduler. It is only able to set the flags. The flags are cleared when the register is read by the BP or during an SDMA reset.</li> <li>The CHNERR[i] bit is set when a DMA request that triggers channel <i>i</i> is received through the corresponding input pins and the EP[i] bit is already set. The EVTERR[i] bit is unaffected if the BP tries to set the EP[i] bit when that EP[i] bit is already set.</li> </ul>

### 41.9.6 Channel DSP Interrupt Mask (SDMABP\_INTRMASK)

Address: 20E\_C000h base + 2Ch offset = 20E\_C02Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### SDMABP\_INTRMASK field descriptions

Field	Description
31–0 DIMASK	The Interrupt Mask Register contains 32 interrupt generation mask bits. If bit DIMASK[i] is set, the DI[i] bit is set and an interrupt is sent to the BP when a DMA request error is detected on channel <i>i</i> (for example, EVTERR[i] is set).

### 41.9.7 DMA Request Error Register (SDMABP\_EVTERRDBG)

Address: 20E\_C000h base + 34h offset = 20E\_C034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CHNERR																															
W

#### SDMABP\_EVTERRDBG field descriptions

Field	Description
31–0 CHNERR	This register is the same as EVTERR except reading it does not clear its contents. This address is meant to be used in debug mode. The BP OnCE may check this register value without modifying it.

## 41.10 SDMA Internal (Core) Memory Map and Internal Register Definitions

The actual SDMA memory mapped registers are summarized in the following sections; for peripherals' memory maps, refer to the respective chapters.

The following definitions serve as a key for the SDMA internal register summary.

## SDMACORE memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
20E_C000	ARM platform Channel 0 Pointer (SDMACORE_MC0PTR)	32	R	0000_0000h	<a href="#">41.10.1/2629</a>
20E_C002	Current Channel Pointer (SDMACORE_CCPtr)	32	R	0000_0000h	<a href="#">41.10.2/2629</a>
20E_C003	Current Channel Register (SDMACORE_CCR)	32	R	0000_0000h	<a href="#">41.10.3/2629</a>
20E_C004	Highest Pending Channel Register (SDMACORE_NCR)	32	R	0000_0000h	<a href="#">41.10.4/2630</a>
20E_C005	External DMA Requests Mirror (SDMACORE_EVENTS)	32	R	0000_0000h	<a href="#">41.10.5/2631</a>
20E_C006	Current Channel Priority (SDMACORE_CCPRI)	32	R	0000_0000h	<a href="#">41.10.6/2632</a>
20E_C007	Next Channel Priority (SDMACORE_NCPRI)	32	R	0000_0000h	<a href="#">41.10.7/2632</a>
20E_C009	OnCE Event Cell Counter (SDMACORE_ECOUNT)	32	R/W	0000_0000h	<a href="#">41.10.8/2633</a>
20E_C00A	OnCE Event Cell Control Register (SDMACORE_ECTL)	32	R/W	0000_0000h	<a href="#">41.10.9/2633</a>
20E_C00B	OnCE Event Address Register A (SDMACORE_EAA)	32	R/W	0000_0000h	<a href="#">41.10.10/2635</a>
20E_C00C	OnCE Event Cell Address Register B (SDMACORE_EAB)	32	R/W	0000_0000h	<a href="#">41.10.11/2635</a>
20E_C00D	OnCE Event Cell Address Mask (SDMACORE_EAM)	32	R/W	0000_0000h	<a href="#">41.10.12/2635</a>
20E_C00E	OnCE Event Cell Data Register (SDMACORE_ED)	32	R/W	0000_0000h	<a href="#">41.10.13/2636</a>
20E_C00F	OnCE Event Cell Data Mask (SDMACORE_EDM)	32	R/W	0000_0000h	<a href="#">41.10.14/2636</a>
20E_C018	OnCE Real-Time Buffer (SDMACORE_RTB)	32	R/W	0000_0000h	<a href="#">41.10.15/2637</a>
20E_C019	OnCE Trace Buffer (SDMACORE_TB)	32	R	0000_0000h	<a href="#">41.10.16/2637</a>
20E_C01A	OnCE Status (SDMACORE_OSTAT)	32	R	0000_0000h	<a href="#">41.10.17/2638</a>
20E_C01C	Channel 0 Boot Address (SDMACORE_MCHN0ADDR)	32	R	0000_0000h	<a href="#">41.10.18/2640</a>
20E_C01D	ENDIAN Status Register (SDMACORE_ENDIANNES)	32	R	0000_0001h	<a href="#">41.10.19/2641</a>
20E_C01E	Lock Status Register (SDMACORE_SDMA_LOCK)	32	R	0000_0000h	<a href="#">41.10.20/2642</a>
20E_C01F	External DMA Requests Mirror #2 (SDMACORE_EVENTS2)	32	R	0000_0000h	<a href="#">41.10.21/2643</a>

### 41.10.1 ARM platform Channel 0 Pointer (SDMACORE\_MC0PTR)

Address: 20E\_C000h base + 0h offset = 20E\_C000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

#### SDMACORE\_MC0PTR field descriptions

Field	Description
31–0 MC0PTR	Contains the address-in the ARM platform memory space-of the initial SDMA context and scripts that are loaded by the SDMA boot script running on channel 0.

### 41.10.2 Current Channel Pointer (SDMACORE\_CCPtr)

Address: 20E\_C000h base + 2h offset = 20E\_C002h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																CCPTR															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

#### SDMACORE\_CCPtr field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–0 CCPTR	Contains the start address of the context data for the current channel: Its value is <i>CONTEXT_BASE</i> + 24* <i>CCR</i> or <i>CONTEXT_BASE</i> + 32* <i>CCR</i> where <i>CONTEXT_BASE</i> = 0x0800. The value 24 or 32 is selected according to the programmed channel scratch RAM size in the register shown in <a href="#">Channel 0 Boot Address (SDMAARM_CHN0ADDR)</a> .

### 41.10.3 Current Channel Register (SDMACORE\_CCR)

Address: 20E\_C000h base + 3h offset = 20E\_C003h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**SDMACORE\_CCR field descriptions**

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4–0 CCR	Contains the number of the current running channel whose context is installed. In the case that the SDMA has finished running the channel and has entered sleep state, CCR will indicate the previous running channel. The PST bits in the OSTAT register indicate when the SDMA is in sleep state.

**41.10.4 Highest Pending Channel Register (SDMACORE\_NCR)**

Address: 20E\_C000h base + 4h offset = 20E\_C004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**SDMACORE\_NCR field descriptions**

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4–0 NCR	Contains the number of the pending channel that the scheduler has selected to run next.

### 41.10.5 External DMA Requests Mirror (SDMACORE\_EVENTS)

#### NOTE

This register is very useful in the case of DMA requests that are active when a peripheral FIFO level is above the programmed watermark. The activation of the DMA request (rising edge) is detected by the SDMA logic and it can enable one or several channels. One of the channels accesses the peripheral and reads or writes a number of data that matches the watermark level (for example, if the watermark is four words, the channel reads or writes four words).

If the channel is effectively executed long after the DMA request was received, reading or writing the watermark number of data may not be sufficient to reset the DMA request (for example, if the FIFO watermark is four and at the channel execution it already contains nine pieces of data). This means no new rising edge may be detected by the SDMA, although there still remains transfers to perform. Therefore, if the channel were terminated at that time, it would not be restarted, causing potential overrun or underrun of the peripheral.

The proposed mechanism is for the channel to check this register after it has performed the "watermark" number of accesses to the peripheral. If the bit for the DMA request that triggers this channel is set, it means there is still another watermark number of data to transfer. This goes on until the bit is cleared. The same script can be used for multiple channels that require this behavior. The script can determine its channel number from the CCR register and infer the corresponding DMA request bit to check. It needs a reference table that is coherent with the request-channel matrix that the ARM platform programmed.

Address: 20E\_C000h base + 5h offset = 20E\_C005h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### SDMACORE\_ECTL field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13 EN	Event Cell Enable. If the EN bit is set, the event cell is allowed to generate debug requests (the cell is awakened). If it is cleared, the event detection unit is disabled and no hardware breakpoint is generated, but matching conditions are still reflected on the emulation pin.  0 Cell is disabled. 1 Cell is enabled.
12 CNT	Event Counter Enable. The event counter enable bit determines if the cell counter is used during the event detection. In order to use the event counter during an event detection process, the event cell counter register should be loaded with a value equal to the number of times minus one that an event occurs before

Table continues on the next page...

**SDMACORE\_ECTL field descriptions (continued)**

Field	Description
	<p>a debug request is sent. After every event detection, the counter is decreased. When the counter reaches the value 0, the event detection cell sends a debug request to the core. The event counter register should be written and the EN bit should be set before each new event detection process uses the event counter.</p> <p>0 Counter is disabled. 1 Counter is enabled.</p>
11–10 ECTC[1:0]	<p>The event cell trigger condition bits select the combination of address and data matching conditions that generate the final address/data condition. During program execution, if this event cell trigger condition goes to 1, a debug request is sent to the SDMA. The EN bit must be set to enable the debug request generation.</p> <p>00 address ONLY 01 data ONLY 10 address AND data 11 address OR data</p>
9–8 DTC[1:0]	<p>The data trigger condition bits define when data is considered matching after comparison with the data register of the event detection unit. The operations are performed on unsigned values.</p> <p>00 equal 01 not equal 10 greater than 11 less than</p>
7–6 ATC[1:0]	<p>The address trigger condition bits select how the two address conditions (addressA and addressB) are combined to define the global address matching condition. The supported combinations are described, as follows.</p> <p>00 addressA ONLY 01 addrA AND addrB 10 addrA OR addrB 11 reserved</p>
5–4 ABTC[1:0]	<p>The Address B Trigger Condition (ABTC) controls the operations performed by address comparator B. All operations are performed on unsigned values. This comparator B outputs the addressB condition.</p> <p>00 equal 01 not equal 10 greater than 11 less than</p>
3–2 AATC[1:0]	<p>The Address A Trigger Condition (AATC) controls the operations performed by address comparator A. All operations are performed on unsigned values. This comparator A outputs the addressA condition.</p> <p>00 equal 01 not equal 10 greater than 11 less than</p>
1–0 ATS[1:0]	<p>The access type select bits define the memory access type required on the SDMA memory bus.</p> <p>00 read ONLY 01 write ONLY 10 read or write 11 -</p>

### 41.10.10 OnCE Event Address Register A (SDMACORE\_EAA)

Address: 20E\_C000h base + Bh offset = 20E\_C00Bh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table continues on the next page...

**SDMACORE\_OSTAT field descriptions (continued)**

Field	Description
	14 Sleep after Reset 15 Restore
11 RCV	After each write access to the real time buffer (RTB), the RCV bit is set. This bit is cleared after execution of an <code>rbuffer</code> command and on a JTAG reset.
10 EDR	This flag is raised when the SDMA has entered debug mode after an external debug request.
9 ODR	This flag is raised when the SDMA has entered debug mode after a OnCE debug request.
8 SWB	This flag is raised when the SDMA has entered debug mode after a software breakpoint.
7 MST	This flag is raised when the OnCE is controlled from the ARM platform peripheral interface. 0 JTAG interface controls the OnCE. 1 ARM platform peripheral interface controls the OnCE.
6–3 Reserved	This read-only field is reserved and always has the value 0.
2–0 ECDR[2:0]	Event Cell Debug Request. If the debug request comes from the event cell, the reason for entering debug mode is given by the EDR bits. The encoding of the EDR bits is useful to find out more precisely why the debug request was generated. A debug request from an event cell is generated for a specific combination of the addressA, addressB, and data conditions; the value of those fields is given by the EDR bits. If all three bits of the EDR are reset, then it did not generate any debug request. If the cell did generate a debug request, then at least one EDR bit is set; the meaning of the encoding is as follows:  0 1 matched addressA condition 1 1 matched addressB condition 2 1 matched data condition

## 41.10.18 Channel 0 Boot Address (SDMACORE\_MCHN0ADDR)

Address: 20E\_C000h base + 1Ch offset = 20E\_C01Ch

### SDMACORE\_MCHN0ADDR field descriptions

Field	Description
31–15 Reserved	This read-only field is reserved and always has the value 0.
14 SMSZ	<p>The bit 14 (Scratch Memory Size) determines if scratch memory must be available after every channel context. After reset, it is equal to 0, which defines a RAM space of 24 words for each channel. All of this area stores the channel context. By setting this bit, 32 words are reserved for every channel context, which gives eight additional words that can be used by the channel script to store any type of data. Those words are never erased by the context switching mechanism.</p> <p>0 24 words per context 1 32 words per context</p>
13–0 CHN0ADDR[13:0]	Contains the address of the channel 0 routine programmed by the ARM platform; it is loaded into a general register at the very start of the boot and the SDMA jumps to the address it contains. By default, it points to the standard boot routine in ROM.

## 41.10.19 ENDIAN Status Register (SDMACORE\_ENDIANNES)

Address: 20E\_C000h base + 1Dh offset = 20E\_C01Dh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												0		APEND	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

### SDMACORE\_ENDIANNES field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value 0.
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 APEND	APEND indicates the endian mode of the Peripheral and Burst DMA interfaces. This bit is tied to logic '1' indicating little-endian mode.  0 - ARM platform is in big-endian mode 1 - ARM platform is in little-endian mode

41.10.20 Lock Status Register (SDMACORE\_SDMA\_LOCK)

Address: 20E\_C000h base + 1Eh offset = 20E\_C01Eh

SDMACORE\_SDMA\_LOCK field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value 0.
0 LOCK	The LOCK bit reports the value of the LOCK bit in the SDMA_LOCK status register. SDMA software may use this value to determine if certain operations such as loading of new scripts is allowed.  0 - LOCK bit clear 1 - LOCK bit set

### 41.10.21 External DMA Requests Mirror #2 (SDMACORE\_EVENTS2)

Address: 20E\_C000h base + 1Fh offset = 20E\_C01Fh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																EVENTS															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMACORE\_EVENTS2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–0 EVENTS	Reflects the status of the SDMA's external DMA requests. It is meant to allow any channel to monitor the states of these SDMA inputs.  This register displays EVENTS 32-47. The separate EVENTS register displays events 0-31.

### 41.11 SDMA Peripheral Registers

Refer to the respective peripherals' chapters for more information.

# Chapter 42

## SiPix Display Controller (SPDC)

### 42.1 Overview

This chapter describes the detailed architecture of the SiPix Display Controller (SPDC) for E-Book application. It provides a detailed description of the SPDC for digital design and software development.

The SPDC provides control signals for the source driver and gate drivers. This IP provides a high performance, low cost solution for SiPix EPDs (Electronic Paper Display). Partial update and concurrent display updates resulting in high responsive screen changes are also implemented for these applications. The SPDC module is defined to co-work in conjunction with the eXPX IP module to form a complete display processing solution, such as rotation and flip function.

#### 42.1.1 Features

The key features of the SPDC are as follows:

- Support 22 resolutions:
  - 800x600, 600x800, 1024x768, 768x1024, 1024x800, 800x1024, 1024x600, 600x1024, 1200x825, 825x1200, 1280x825, 825x1280, 1280x800, 800x1280, 1280x768, 768x1280, 1280x960, 960x1280, 1280x1024, 1024x 1280, 1600x1200, 1200x1600
- Support driver IC:
  - Source driver: K7600
  - Gate driver: MEXI2300, AUO-G5901
  - Source driver + Gate driver: K7900, K7902, K7903
- Industry standard bus interfaces (AMBA AHB and APB)
- Low-power mode operation via architectural clock gating
- Support full and partial update mode

### 42.1.2 Block Diagram

The top-level view of the SPDC is shown in figure below.

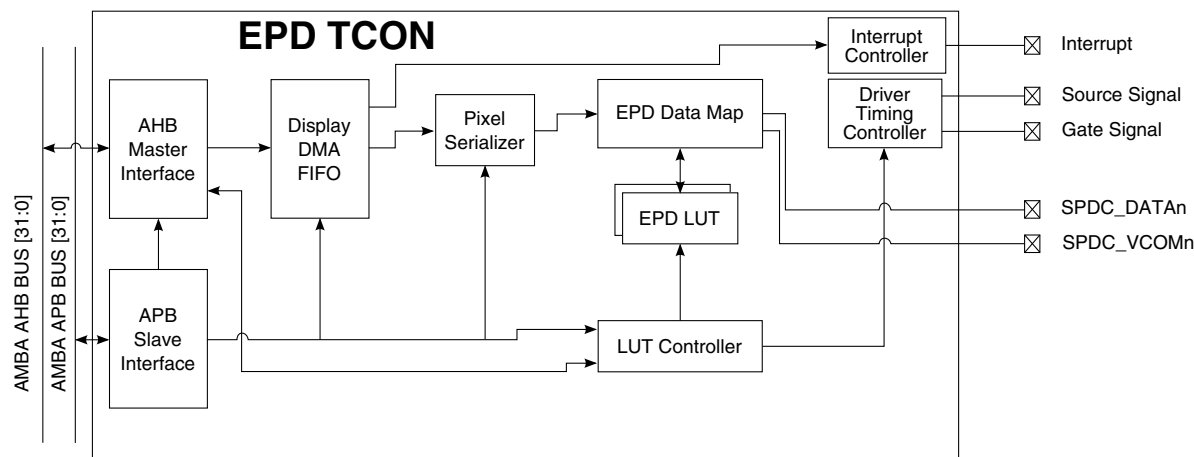

Figure 42-1. Overall Block Diagram of SPDC

The SPDC can be separated into three major groups. The first group, including the AHB Master Interface, the APB Slave Interface, and the Display DMA FIFO, is responsible for accessing the image pixel data from DRAM memory and receives the APB register setting from CPU. The second group, including Pixel Serializer, EPD Data Map, EPD LUT, and LUT Controller, is responsible for using the image pixel data to look up waveform LUT to generate driving waveform of SiPix EPD panel. The last group includes Driver Timing Controller and Interrupt Controller, and is responsible for generating the driver driving timing and issuing all kind of interrupt signals.

### 42.2 External Signals

Table 42-1. SPDC I/O Port

Function.	Port Name	I/O	Width	Description
Driver Control/Data Signal	SPDC_CL	O	1	Driver Clock
	SPDC_XDIOR	O	1	Source driver data right start pulse
	SPDC_XDIOL	O	1	Source driver data left start pulse
	SPDC_LD	O	1	Source driver load signal (latch data to DAC)

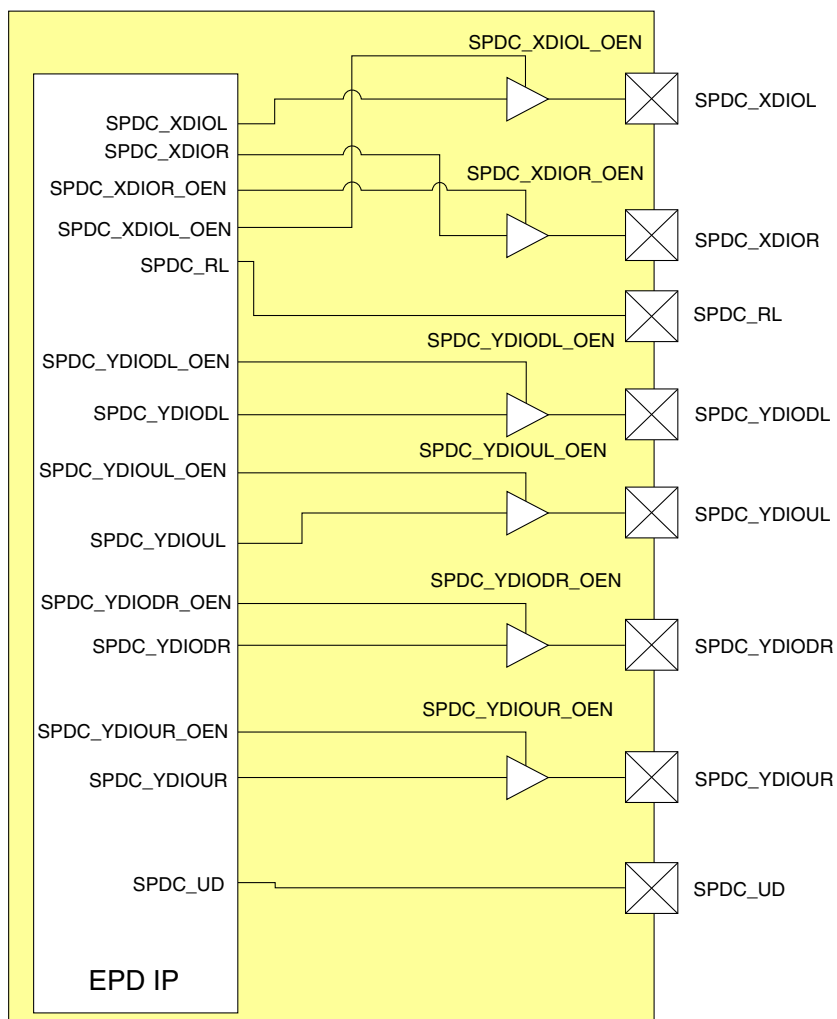

Table continues on the next page...

**Table 42-1. SPDC I/O Port (continued)**

	SPDC_RL (SOE)	O	1	Panel scan direction [0: Right to Left, 1: Left to Right] (could be setting to SOE pin - Source driver output enable)
	SPDC_YDIODL	O	1	Left gate driver down start pulse
	SPDC_YDIOUL	O	1	Left gate driver up start pulse
	SPDC_YDIOUR	O	1	Right gate driver down start pulse
	SPDC_YDIOUR	O	1	Right gate driver up start pulse
	SPDC_YOEL	O	1	Left gate driver output enable
	SPDC_SOE (YOER)	O	1	Source driver output enable (Can be set to YOER pin - Right gate driver output enable)
	SPDC_YCKL	O	1	Left gate driver clock
	SPDC_YCKR	O	1	Right gate driver clock
	SPDC_UD (SOE)	O	1	Gate scan direction [0: Up to Down, 1: Down to Up] (Can be set to SOE pin - Source driver output enable)
	SPDC_VCOM	O	2	SPDC_VCOM selection
	SPDC_DATA	O	16	Driver data

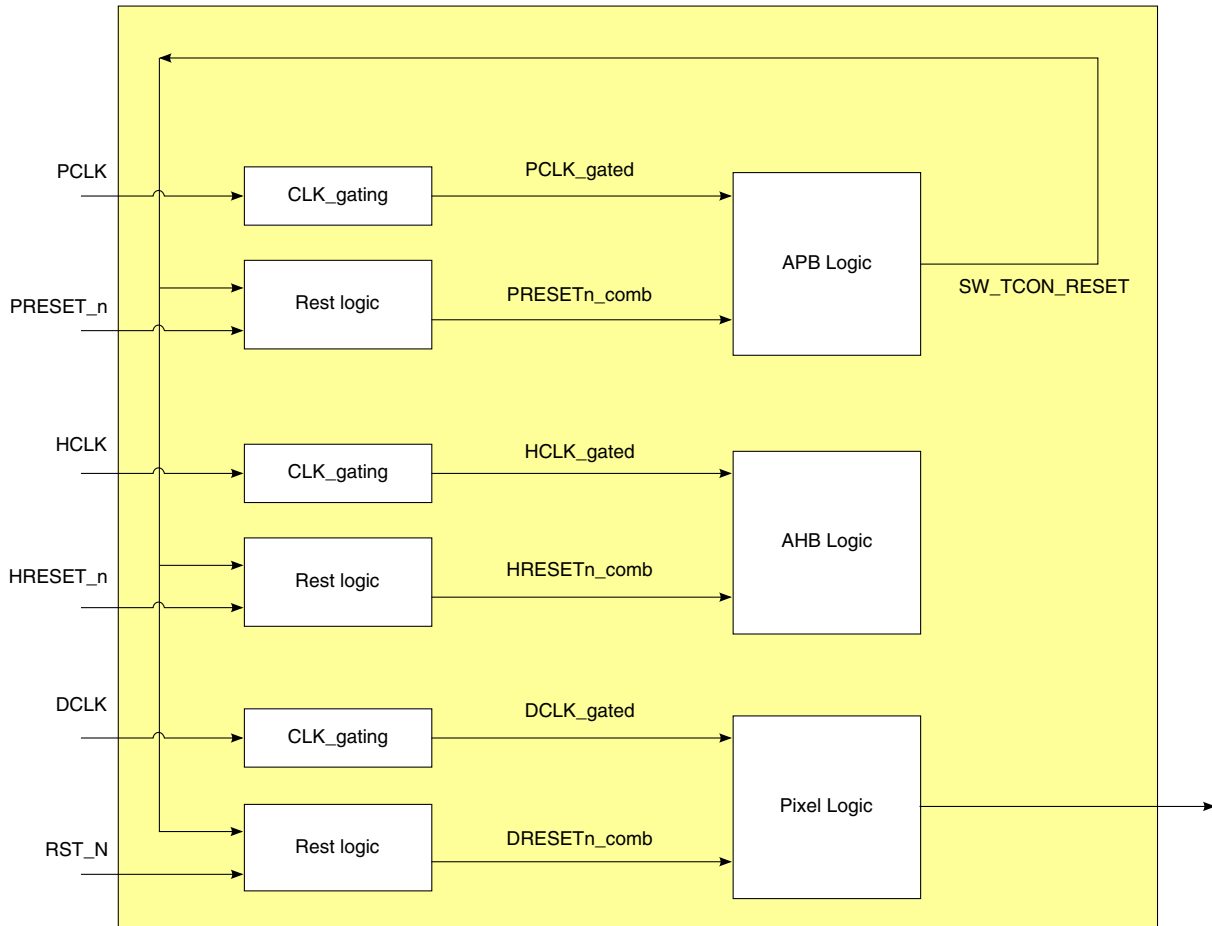

## 42.2.1 Chip Level Connection

**Figure 42-3. Clock and Reset Signal Connection**

### 42.2.2 Chip Level Pinout List

Table found here shows the pinout list and pinout type of SPDC.

**Table 42-2. SPDC Pinout List**

Pad #	Name	output	output enable (Low Active)	pad type
1	SPDC_CL	SPDC_CL	0	Type 1
2	SPDC_XDIOR	SPDC_XDIOR	XDIOR_OEN	Type 6
3	SPDC_XDIOL	SPDC_XDIOL	XDIOL_OEN	Type 6
4	SPDC_LD	SPDC_LD	0	Type 1

*Table continues on the next page...*

**Table 42-2. SPDC Pinout List  
(continued)**

5	SPDC_RL	SPDC_RL	0	Type 1
6	SPDC_YDIODL	SPDC_YDIODL	SPDC_YDIODL_OEN	Type 6
7	SPDC_YDIOUL	SPDC_YDIOUL	SPDC_YDIOUL_OEN	Type 6
8	SPDC_YDIODR	SPDC_YDIODR	SPDC_YDIODR_OEN	Type 6
9	SPDC_YDIOUR	SPDC_YDIOUR	SPDC_YDIOUR_OEN	Type 6
10	SPDC_YOEL	SPDC_YOEL	0	Type 1
11	SPDC_YOER	SPDC_YOER	0	Type 1
12	SPDC_YCKL	SPDC_YCKL	0	Type 1
13	SPDC_YCKR	SPDC_YCKR	0	Type 1
14	SPDC_UD	SPDC_UD	0	Type 1
15	SPDC_VCOM1	SPDC_VCOM1	0	Type 1
16	SPDC_VCOM0	SPDC_VCOM0	0	Type 1
17	SPDC_DATA15	SPDC_DATA15	0	Type 1
18	SPDC_DATA14	SPDC_DATA14	0	Type 1
19	SPDC_DATA13	SPDC_DATA13	0	Type 1
20	SPDC_DATA12	SPDC_DATA12	0	Type 1
21	SPDC_DATA11	SPDC_DATA11	0	Type 1
22	SPDC_DATA10	SPDC_DATA10	0	Type 1
23	SPDC_DATA09	SPDC_DATA09	0	Type 1
24	SPDC_DATA08	SPDC_DATA08	0	Type 1
25	SPDC_DATA07	SPDC_DATA07	0	Type 1
26	SPDC_DATA06	SPDC_DATA06	0	Type 1
27	SPDC_DATA05	SPDC_DATA05	0	Type 1
28	SPDC_DATA04	SPDC_DATA04	0	Type 1
29	SPDC_DATA03	SPDC_DATA03	0	Type 1
30	SPDC_DATA02	SPDC_DATA02	0	Type 1
31	SPDC_DATA01	SPDC_DATA01	0	Type 1
32	SPDC_DATA00	SPDC_DATA00	0	Type 1

## 42.3 Software Programming Model

This section intends to introduce the details of driving an SPDC IP using software.

### 42.3.1 SPDC Initial Setup Programming

Before starting to drive the EPD panel using SPDC IP, the system settings need to be initialized by the software. The SPDC initial setup flow is described as follows:

1. Step 1 - Configure the SPDC's working memory in DDR memory from kernel space. For a detailed description, see [Working Memory and Bus Bandwidth Requirements](#).
2. Step 2 - Move the waveform LUT from flash to DDR memory. For a detailed description, see [Reading SiPix EPD Driving Waveform LUT](#).
3. Step 3 - Driving the driver IC power sequence. For a detailed description, see [SiPix EPD Panel Power Sequence Control](#).
4. Step 4 - Configure the SPDC system clock. For a detailed description, see [SPDC System Clock Configuration](#).

5. Step 5 - Turn off the clock gating function (low power mode). For a detailed description, see [Clock Gating Architecture Configuration](#).
6. Step 6 - Configure the interrupt setting. For a detailed description, see [Interrupts Configuration](#).
7. Step 7 - Send some basic initial setting to SPDC, such as TCON initial setting and working frame buffer address registers. For a detailed description, see [Initial Configuration Command Sequence](#).

## 42.3.1.1 Working Memory and Bus Bandwidth Requirements

### 42.3.1.1.1 SPDC Working Memory Buffer

Five kinds of working memory buffers will be accessed by SPDC during panel screen updating at most. They are all expected to reside in system memory, such as external DDR memory, SDRAM, DRAM. And each has particular requirements for gray and color (RGBW) mode:

#### 42.3.1.1.1.1 GRAY MODE

- Next Frame Memory Buffer -The next frame memory buffer, which is pointed by SPDC\_NEXT\_BUF and it must have Panel Resolution (Height x Width) / 2 bytes allocation in system memory (WORD-ALIGN). This buffer is only used to store the next image pixel data. That is, end user put the image data which want to be shown on panel in this memory. The figure below shows the pixel data arrangement in next frame memory buffer.

Bit	B[31:28]	B[27:24]	B[23:20]	B[19:16]	B[15:12]	B[11:8]	B[7:4]	B[3:0]
Pixel	P8	P7	P6	P5	P4	P3	P2	P1

**Figure 42-7. Pixel Data Arrangement in Next Frame Memory Buffer**

- Current Frame Memory Buffer -The current frame memory buffer, which is pointed by SPDC\_CURRENT\_BUF and it must have Panel Resolution (Height x Width) / 2 bytes allocation in system memory (WORD-ALIGN). This buffer is only used to store the current image pixel data. (The content is showing on panel)
- Previous Frame Memory Buffer -The previous frame memory buffer, which is pointed by SPDC\_PREVIOUS\_BUF and it must have Panel Resolution (Height x Width) / 2 bytes allocation in system memory (WORD-ALIGN). This buffer is only used to store the previous image pixel data. (The content had shown on panel)
- Counter Frame Memory Buffer - The counter frame memory buffer, which is pointed by SPDC\_FRM\_CNT\_BUF and it must have Panel Resolution (Height x Width)

bytes allocation in system memory (WORD-ALIGN). This buffer is only used to record the frame counter data of each pixel in mode 4 (High Speed Handwriting Mode).

- **LUT Memory Buffer** - The waveform LUT memory buffer, which is pointed by SPDC\_LUT\_BUF and it must have 2 Mbytes allocation in system memory (WORD-ALIGN). This buffer is used to store the SPDC driving waveform data. The figure below shows the LUT waveform data arrangement in LUT memory buffer.

Bit	B[31:24]	B[23:16]	B[15:8]	B[7:0]
Waveform Data	Data 4	Data 3	Data 2	Data 1

**Figure 42-8. LUT Waveform Data Arrangement in LUT Memory Buffer**

The total working memory requirements in gray mode are given as follows (in bytes):

- $(\text{Panel Resolution (Height x Width)} \times 2.5) + 2 \text{ M (bytes)}$

#### 42.3.1.1.1.2 COLOR MODE

In color mode, it can not use the mode 4 (High Speed Handwriting mode) to update panel screen. So it didn't need to set the counter frame memory buffer.

- **Next Frame Memory Buffer** -The next frame memory buffer, which is pointed by SPDC\_NEXT\_BUF and it must have Panel Resolution (Height x Width) x 2 bytes allocation in system memory (WORD-ALIGN). This buffer is only used to store the next image pixel data. That is, the end user put the image data which want to be shown on the panel in this memory. The Figure 45-7 shows the pixel data arrangement in next frame memory buffer.

Bit	B[31:28]	B[27:24]	B[23:20]	B[19:16]	B[15:12]	B[11:8]	B[7:4]	B[3:0]
Pixel	R2	G2	B2	W2	R1	G1	B1	W1

**Figure 42-9. Pixel Data Arrangement in Next Frame Memory Buffer**

- **Current Frame Memory Buffer** -The current frame memory buffer, which is pointed by SPDC\_CURRENT\_BUF and it must have Panel Resolution (Height x Width) x 2 bytes allocation in system memory (WORD-ALIGN). This buffer is only used to store the current image pixel data. (The content is showing on panel)
- **Previous Frame Memory Buffer** -The previous frame memory buffer, which is pointed by SPDC\_PREVIOUS\_BUF and it must have Panel Resolution (Height x

Width) x 2 bytes allocation in system memory (WORD-ALIGN). This buffer is only used to store the previous image pixel data. (The content had shown on panel)

- LUT Memory Buffer - The waveform LUT memory buffer, which is pointed by SPDC\_LUT\_BUF and it must have 2 Mbytes allocation in system memory (WORD-ALIGN). This buffer is used to store the SPDC driving waveform data. The Figure 45-6 shows the LUT waveform data arrangement in LUT memory buffer.

In summary, the total working memory requirements in color mode are given as follows (in bytes):

- (Panel Resolution (Height x Width) x 6 ) + 2 M (bytes)

### NOTE

Software designer should always operate with next frame memory buffer, and the SPDC IP will update current/previous/counter frame memory buffer automatically.

#### 42.3.1.1.2 Bus Bandwidth Calculation

The maximum bandwidth scenario involves processing mode 4 (High Speed Handwriting Mode) while end user is performing handwriting operations. The mode 4 bandwidth could be calculated as follows:

- Current Frame Memory - Panel Resolution (Height x Width) x Frame Rate (50 Hz) x Per Pixel Size (0.5 bytes)
- Previous Frame Memory - Panel Resolution (Height x Width) x Frame Rate (50 Hz) x Per Pixel Size (0.5 bytes)
- Counter Frame Memory - Panel Resolution (Height x Width) x Frame Rate (50 Hz) x Per Pixel Size (1 bytes) x Concurrently Read and Write (2)

In summary, the total maximum bandwidth requirements in mode 4 are given as follows (in bytes):

- Panel Resolution (Height x Width) x Frame Rate (50 Hz) x 3 (bytes). For example: when 1600 x 1200 resolution in mode 4, the maximum bandwidth requirement is 1600 x 1200 x 50 x 3 (bytes) = 288 M (bytes)

#### 42.3.1.2 Reading SiPix EPD Driving Waveform LUT

The system should move the LUT from flash to system memory, and then system needs to record the LUT start address in system memory.

Because the system need to send it to SPDC\_LUT\_BUF register when SPDC initial setup flow during Step 7.

### 42.3.1.3 SiPix EPD Panel Power Sequence Control

It is assumed that the driver layers will control the driver IC power on/off sequence by the GPIO interface.

The maximum GPIO pins for power on/off sequence are total need 10 pins.

The following figure shows the latest power on/off sequence and the software designer should refer to this figure to control the SiPix EPD panel power.

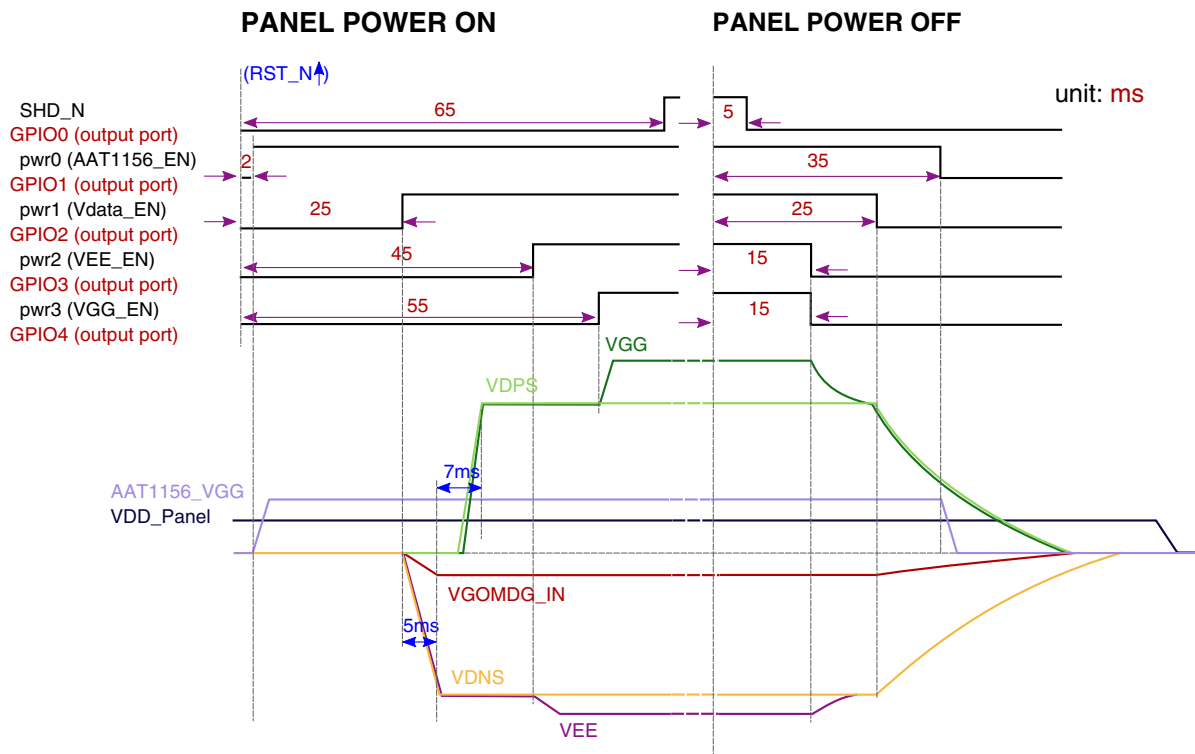

Figure 42-10. Latest Power On/Off Sequence for K7902 Driver IC

#### NOTE

The driver IC VDD should be turned on before analog power. The power on/off sequence may have changed with different versions of the power board.

### 42.3.1.4 SPDC System Clock Configuration

The SPDC supports a number of resolutions. Each resolution forces a particular SPDC systems clock rate (DCLK).

Table 42-3 shows default blanking timing setting of SPDC in each resolution and Table 42-4 shows the minimum blanking timing setting of SPDC in each resolution.

**Table 42-3. System clock required in each resolution (for default blanking timing)**

Resolution				Ideal DCLK Frequency (MHz)	Ideal Frame Rate (Hz)
H	V	H_Blanking	V_Blanking		
800	600	520	10	40.26	50
600	800	400	10	40.50	50
1024	600	300	10	40.38	50
600	1024	180	10	40.33	50
1024	768	20	10	40.61	50
768	1024	25	10	41.00	50
1024	800	10	10	41.88	50
800	1024	10	10	41.88	50
1280	768	50	10	51.74	50
768	1280	50	10	52.76	50
1200	825	50	10	52.19	50
825	1200	50	10	52.94	50
1280	800	50	10	53.87	50
800	1280	50	10	54.83	50
1280	825	50	10	55.53	50
825	1280	50	10	56.44	50
1280	960	50	10	64.51	50
960	1280	50	10	65.15	50
1280	1024	50	10	68.76	50
1024	1280	50	10	69.27	50
1600	1200	50	10	99.83	50
1200	1600	50	10	100.63	50

**Table 42-4. System clock required in each resolution (for minimum blanking timing)**

Resolution				Ideal DCLK Frequency (MHz)	Ideal Frame Rate (Hz)
H	V	H_Blanking	V_Blanking		
800	600	10	10	24.71	50
600	800	10	10	24.71	50
1024	600	10	10	31.54	50
600	1024	10	10	31.54	50
1024	768	10	10	40.22	50

1280	1024	10	10	66.69	50
1024	1280	10	10	66.69	50
1600	1200	10	10	97.41	50
1200	1600	10	10	97.41	50

### 42.3.1.5 Clock Gating Architecture Configuration

The SPDC includes hardware controlled automatic clock gating throughout the design.

This clock gating function will gate off all clocks of sequential elements (flip-flops) when the display content is not being updated. This tier of clock gating is useful for reducing power consumption. The SPDC provides clock-gating feature that could be controlled by the software designer.

Because the SPDC hardware default setting will automatic gated-off all clocks that the software designer need to send SPDC\_SW\_GATE\_CLK setting to clear the SPDC\_SW\_GATE\_CLK[GATING\_ALL\_CLK\_EN] field at initial being to use SPDC.

If the application has finished all updates, the software designer can re-enable the gated-off all clocks function by setting the SPDC\_SW\_GATE\_CLK[GATING\_ALL\_CLK\_EN] field to save power.

#### NOTE

All screen updates must be complete before the software designer can place the SPDC into low power mode.

When the application is ready to send more screen updates, the software designer can immediately re-enable the SPDC by clearing the `SPDC_SW_GATE_CLK[GATING_ALL_CLK_EN]` field to un-gating all clocks. This un-gating of all clocks is immediate and the software designer is free to send update requests to SPDC.

### 42.3.1.6 Interrupts Configuration

The SPDC has a single interrupt signal intended to be connected to a system interrupt controller.

The interrupt will be asserted by SPDC as long as an unmasked interrupt source is active.

#### 42.3.1.6.1 Interrupt Sources

The SPDC has four kinds of unique interrupt sources. Each interrupt source has a particular interrupt status bit which can be read in the `SPDC_INT_ST_CLR` register. When an interrupt event happens, the appropriate bit within the `SPDC_INT_ST_CLR` register is automatically asserted by SPDC. Each of the bits in `SPDC_INT_ST_CLR` register is first AND'ed with its enable bit (in `SPDC_INT_EN`), and then all the masked bits are logically OR'ed together to generate the final single interrupt signal output to the system interrupt controller.

#### 42.3.1.6.2 Enable and Disable Interrupts

Each of the SPDC interrupt sources can be individually enable through the bits in the `SPDC_INT_EN` register. By the way, if an interrupt source is masked out (`SPDC_INT_EN` bit set to 0), its status will not be available in the `SPDC_INT_ST_CLR` register and the interrupt signal will not be asserted.

#### 42.3.1.6.3 Handle and Clear Interrupts

When the software interrupt service routine is entered as a result of a SPDC interrupt, it should read the `SPDC_EPD_INT_ST_CLR` interrupt status register. Once the interrupt has been handled, the software designer should clear the interrupt signal by writing to `SPDC_EPD_INT_ST_CLR` register (set the corresponding interrupt bit to 1).

### 42.3.1.7 Initial Configuration Command Sequence

Before the application starts to screen an update, the SPDC should be configured appropriately.

These rudimentary setup steps are:

1. Send SPDC\_SW\_GATE\_CLK register setting; Disable the clock-gating function.
2. Send SPDC\_INT\_EN register setting; Enable or disable the interrupt function.
3. Send SPDC\_TEMPER\_SETTING register setting; Configure the operated environment temperature.
4. Send SPDC\_NEXT\_BUFF register setting; Configure the next frame memory buffer start address in system memory.
5. Send SPDC\_CURRENT\_BUFF register setting; Configure the current frame memory buffer start address in system memory.
6. Send SPDC\_PREVIOUS\_BUFF register setting; Configure the previous frame memory buffer start address in system memory.
7. Send SPDC\_FRM\_CNT\_BUFF register setting; Configure the counter frame memory buffer start address in system memory.
8. Send SPDC\_LUT\_BUFF register setting; Configure the LUT memory buffer start address in system memory. (If the SPDC\_INT\_EN[LUT\_DOWNLOAD\_FINISH\_INT\_EN] is set to 1, the LUT download finish interrupt will be asserted after this step finish. So that the software designer should clear that interrupt bit field SPDC\_INT\_ST\_CLR[LUT\_DOWNLOAD\_FINISH\_INT\_CLR] after detected the interrupt signal rising.)
9. Send SPDC\_PANEL\_INIT\_SET register setting; Configure the panel resolution, driver scan direction, etc. The most important thing is set the SPDC\_PANEL\_INIT\_SET[POWER\_READY] to 1. (If the SPDC\_INT\_EN[TCON\_INIT\_FINISH\_INT\_EN] is set to 1, the SPDC initialize finish interrupt will be asserted after this step finish. So that the software designer should clear that interrupt bit field SPDC\_INT\_ST\_CLR[TCON\_INIT\_FINISH\_INT\_CLR] after detected the interrupt signal rising.)

### 42.3.2 Display Update Programming

### 42.3.2.1 Basic Waveform Mode Introduction

This section will introduce some typical basic waveform modes for software application development. There are descriptions include mode 0, mode 1, mode 2 and mode 4 given as following:

#### 42.3.2.1.1 Mode 0 - Gray refresh mode with flashing

Features of mode 0:

- 16 level gray (4-bit), foreground is 4 bit and background is 4 bit.
- Require Local update (x,y,w,l) format from Host.
- Black & white Flashing.
- For high quality images.

Figure 45-9 is an example of screen update with mode 0 waveform:

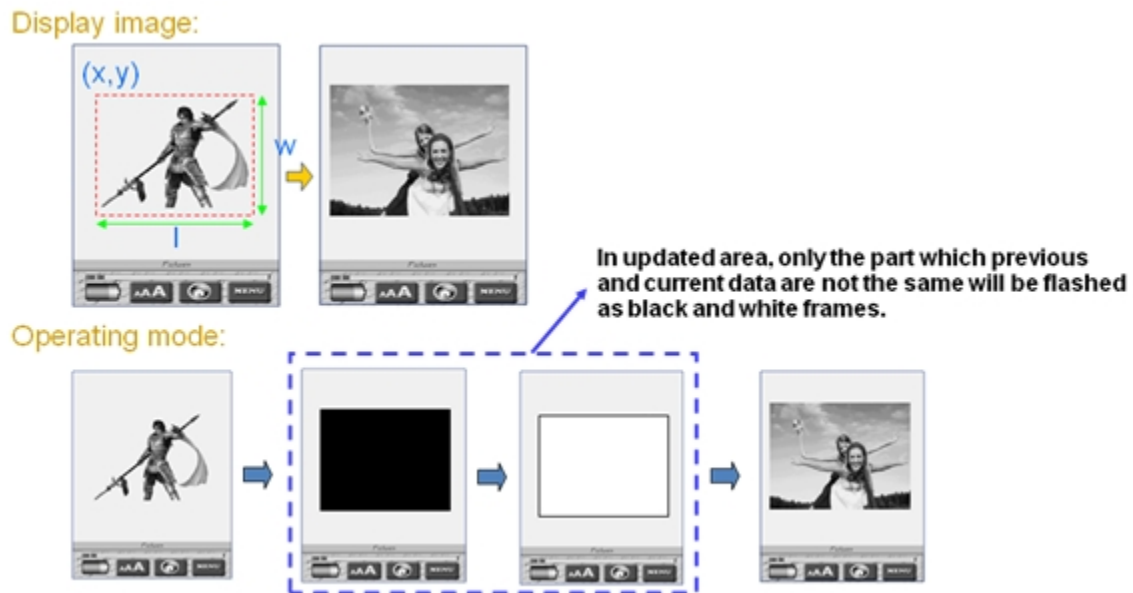

Figure 42-11. The example of screen update with mode 0 waveform

#### 42.3.2.1.2 Mode 1 - Gray refresh mode without flashing

Features of mode 1:

- 16 level gray (4-bit), foreground is 4 bit and background is 4 bit.
- Require Local update (x,y,w,l) format from Host.
- No flashing
- Suit for text/image.

Figure below is an the example of screen update with mode 1 waveform:

**Figure 42-12. The example of screen update with mode 1 waveform**

#### 42.3.2.1.3 Mode 2 - Text mode

Features of mode 2:

- Foreground is 2bit(4 gray level), background is 4 bit
- Require Local update (x,y,w,l) format from Host
- No flashing.
- Suit for text/menu.

Figure below is an the example of screen update with mode 2 waveform:

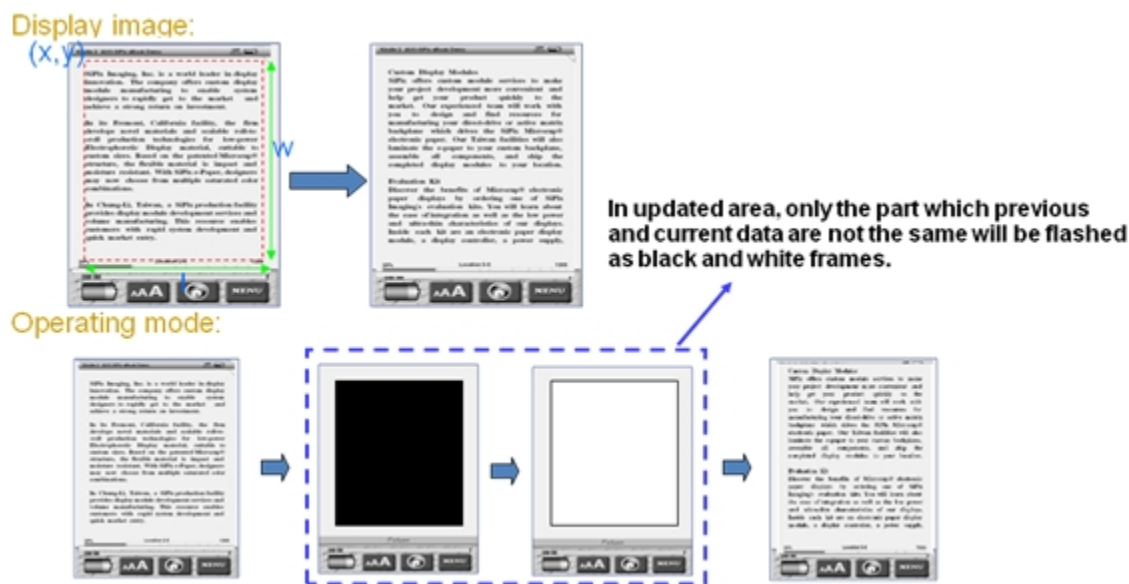

Figure 42-13. The example of screen update with mode 2 waveform

#### 42.3.2.1.4 Mode 4 - High speed handwriting mode

Features of mode 4:

- Handwrite is from white to black, background is 4 bit
- Require Local update (x,y,w,l) format from Host
- No flashing.
- Fast response for handwriting.

Figure below is an the example of screen update with mode 4 waveform:

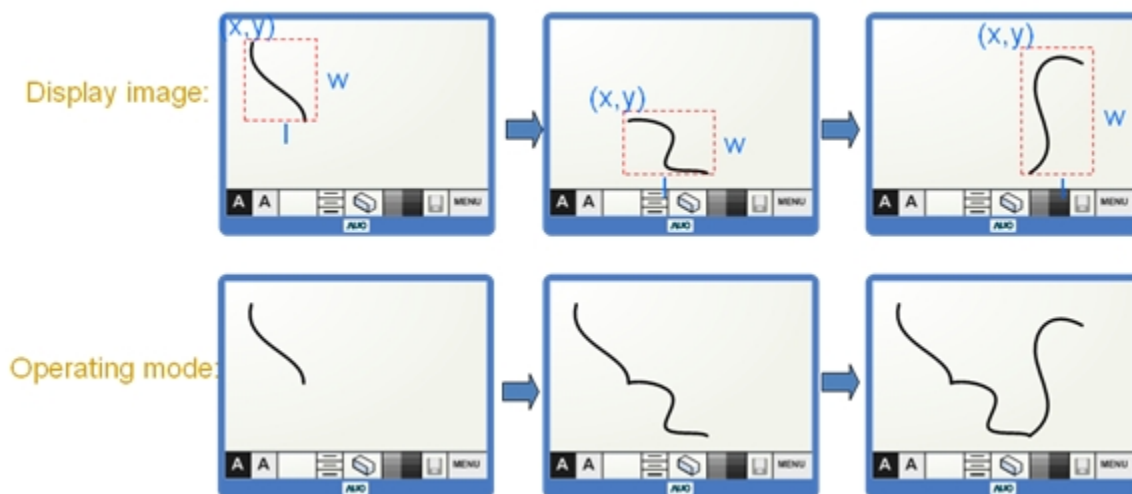

Figure 42-14. The example of screen update with mode 4 waveform

**NOTE**

This section just introduces typical waveform features of each mode but these mode features are maybe changed with different LUT versions.

### **42.3.2.2 Initiating a Display Flow in Normal and High Speed Handwriting Mode**

The typical flow for performing a normal display update mode includes the following steps:

1. Step 1 - Read the SPDC\_STATUS[EPD\_TCON\_BUSY\_N] bit field, it must be 1. The SPDC cannot process new updates if it is currently processing an update.
2. Step 2 - Make sure that the correct temperature is selected and has been written to SPDC\_TEMPER\_SETTING register. The SPDC needs to update the panel screen with the correct environment temperature.
3. Step 3 - The software designer should put the update image into next frame memory buffer in correct location base on the update coordinate (SPDC\_UPDATE\_X\_Y[COORDINATE\_X], SPDC\_UPDATE\_X\_Y[COORDINATE\_Y], SPDC\_UPDATE\_W\_H[WIDTH], SPDC\_UPDATE\_W\_H[HEIGHT]).
4. Step 4 - Send the update coordinate settings such as SPDC\_UPDATE\_X\_Y[COORDINATE\_X], SPDC\_UPDATE\_X\_Y[COORDINATE\_Y], SPDC\_UPDATE\_W\_H[WIDTH], SPDC\_UPDATE\_W\_H[HEIGHT] to SPDC.
5. Step 5 - Send the SPDC\_DISP\_TRIGGER settings to SPDC. It includes screen update trigger and selected waveform mode.

Here we also provide the typical flow for a high speed handwriting mode (mode 4), it is given as following:

1. Step 1 - Make sure that the correct temperature is selected and has been written to SPDC\_TEMPER\_SETTING register. The SPDC needs to update the panel screen with the correct environment temperature.
2. Step 2 - The software designer should put the update image into next frame memory buffer in correct location base on the update coordinate (SPDC\_UPDATE\_X\_Y[COORDINATE\_X], SPDC\_UPDATE\_X\_Y[COORDINATE\_Y], SPDC\_UPDATE\_W\_H[WIDTH], SPDC\_UPDATE\_W\_H[HEIGHT]).
3. Step 3 - Send the update coordinate settings such as SPDC\_UPDATE\_X\_Y[COORDINATE\_X],

SPDC\_UPDATE\_X\_Y[COORDINATE\_Y], SPDC\_UPDATE\_W\_H[WIDTH], SPDC\_UPDATE\_W\_H[HEIGHT] to SPDC.

4. Step 4 - Send the SPDC\_DISP\_TRIGGER settings to SPDC. It includes screen update trigger and selected waveform mode (here should be mode 4).

The difference between a high speed handwriting mode and a normal display update is that the high speed handwriting mode does not need to use the SPDC\_STATUS[EPD\_TCON\_BUSY\_N] status or the update finish interrupt (SPDC\_INT\_ST\_CLR[UPDATE\_FINISH\_INT\_CLR]). This is because in this mode, SPDC will immediately update the panel screen when the software designer sends the screen update trigger (SPDC\_DISP\_TRIGGER[DISP\_TRIG]). It does not need to wait until the SPDC has finished the current screen update (SPDC\_STATUS[EPD\_TCON\_BUSY\_N] set to 1). This makes it much faster than other waveform modes. It is always used in handwriting applications.

### 42.3.2.3 Concurrent Update

The concurrent update in SPDC controller is not a really "concurrent". The controller can accept multiple update command but only can serve one update at a time. Instead of doing the update one by one, the controller will merge all the pending commands into one command. Below are the detailed description of "concurrent update" feature.

1. The controller can accept up to 16 update command;
2. When there is no active command being processed, the first command will start immediately after it is sent to the controller;
3. When there is active command being processed, controller can still accept 15 new update commands, but these command will be pending;
4. When the current active command is done, all the pending commands will be merged into one command automatically by the controller and started automatically;
5. When multiple pending commands are merged, the last command's update mode will be used as the mode for merged command;
6. When multiple pending commands are merged, the update region for merged command will be a rectangle outline just to include the update regions of all the update commands;
7. When a pixel is covered by multiple pending commands' update region, the pixel value in the later update command will be used;

## 42.4 SPDC Memory Map/Register Definition

### SPDC Register Format Summary

**SPDC memory map**

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
20E_8000	Display Trigger (SPDC_DISP_TRIGGER)	32	R/W	0000_0000h	<a href="#">42.4.1/2668</a>
20E_8004	Display Coordinate (SPDC_UPDATE_X_Y)	32	R/W	0000_0000h	<a href="#">42.4.2/2669</a>
20E_8008	Display Area Size (SPDC_UPDATE_W_H)	32	R/W	0000_0000h	<a href="#">42.4.3/2669</a>
20E_800C	LUT Parameter Update (SPDC_LUT_PARA_UPDATE)	32	R/W	0000_0000h	<a href="#">42.4.4/2670</a>
20E_8010	Display Normal Operation (SPDC_OPERATE)	32	R/W	0000_0000h	<a href="#">42.4.5/2670</a>
20E_8014	SPDC Initial Setting (SPDC_PANEL_INIT_SET)	32	R/W	0000_2000h	<a href="#">42.4.6/2671</a>
20E_8018	Environment Temperature (SPDC_TEMPER_SETTING)	32	R/W	0000_0000h	<a href="#">42.4.7/2674</a>
20E_801C	Next Frame Memory Address (SPDC_NEXT_BUF)	32	R/W	0000_0000h	<a href="#">42.4.8/2675</a>
20E_8020	Current Frame Memory Address (SPDC_CURRENT_BUF)	32	R/W	0000_0000h	<a href="#">42.4.9/2675</a>
20E_8024	Previous Frame Memory Address (SPDC_PREVIOUS_BUFF)	32	R/W	0000_0000h	<a href="#">42.4.10/2676</a>
20E_8028	Counter Frame Memory Address (SPDC_FRM_CNT_BUFF)	32	R/W	0000_0000h	<a href="#">42.4.11/2676</a>
20E_802C	LUT Memory Address (SPDC_LUT_BUFF)	32	R/W	0000_0000h	<a href="#">42.4.12/2676</a>
20E_8030	Interrupt Enable (SPDC_INT_EN)	32	R/W	0000_0000h	<a href="#">42.4.13/2677</a>
20E_8034	Interrupt Status & Clear (SPDC_INT_ST_CLR)	32	R/W	0000_0000h	<a href="#">42.4.14/2678</a>
20E_803C	SPDC Operation Status (SPDC_STATUS)	32	R	0000_0000h	<a href="#">42.4.15/2680</a>
20E_8040	Panel Type Related Information (SPDC_PANEL_TYPE_VER)	32	R	0000_0000h	<a href="#">42.4.16/2681</a>
20E_8044	SPDC IP Version (SPDC_TCON_VER)	32	R	0000_0000h	<a href="#">42.4.17/2682</a>
20E_8048	All Clock Gating Enable (SPDC_SW_GATE_CLK)	32	R/W	0000_0001h	<a href="#">42.4.18/2683</a>

## 42.4.1 Display Trigger (SPDC\_DISP\_TRIGGER)

Address: 20E\_8000h base + 0h offset = 20E\_8000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved												FLASH_SET	EPD_MODE		DISP_TRIG
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

### SPDC\_DISP\_TRIGGER field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 FLASH_SET	Judge EPD screen update will be flashed or not in mode 7 0x0 NO_FLASH - It will not be flashed screen update in mode 7 0x1 FLASH - It will be flashed screen update in mode 7
3–1 EPD_MODE	EPD update mode setting 0x0 MODE_0 - It will be displayed with mode 0 waveform 0x1 MODE_1 - It will be displayed with mode 1 waveform 0x2 MODE_2 - It will be displayed with mode 2 waveform 0x3 MODE_3 - It will be displayed with mode 3 waveform 0x4 MODE_4 - It will be displayed with mode 4 waveform (High Speed Handwriting Mode) 0x5 MODE_5 - It will be displayed with mode 5 waveform 0x7 MODE_7 - It will be displayed with mode 7 waveform
0 DISP_TRIG	EPD screen update trigger When set to "1" it will trigger TCON start to display image on panel.

## 42.4.2 Display Coordinate (SPDC\_UPDATE\_X\_Y)

Address: 20E\_8000h base + 4h offset = 20E\_8004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved				COORDINATE_X												RSVD1				COORDINATE_Y											
W	Reserved				COORDINATE_X												RSVD1				COORDINATE_Y											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

### SPDC\_UPDATE\_X\_Y field descriptions

Field	Description
31–28 -	This field is reserved. Reserved
27–16 COORDINATE_X	Horizontal coordinate of update region (minimum: 1) X should be 4n + 1 format where n is integer
15–12 RSVD1	Reserved
11–0 COORDINATE_Y	Vertical coordinate of update region (minimum: 1) If image have rotated counterclockwise 90 Y should be 4n + 1 format where n is integer

## 42.4.3 Display Area Size (SPDC\_UPDATE\_W\_H)

Address: 20E\_8000h base + 8h offset = 20E\_8008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved				WIDTH												Reserved				HEIGHT											
W	Reserved				WIDTH												Reserved				HEIGHT

### SPDC\_UPDATE\_W\_H field descriptions

Field	Description
31–28 -	This field is reserved. Reserved
27–16 WIDTH	Width of update region W should be 4n format where n is integer
15–12 -	This field is reserved. Reserved
11–0 HEIGHT	Height of update region If image have rotated counterclockwise 90 L should be 4n format where n is integer

## 42.4.4 LUT Parameter Update (SPDC\_LUT\_PARA\_UPDATE)

Address: 20E\_8000h base + Ch offset = 20E\_800Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved																LUT_PARAMETER_UPDATED_ADDR								LUT_PARAMETER_UPDATED_VALUE							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

**SPDC\_LUT\_PARA\_UPDATE field descriptions**

Field	Description
31–16 -	This field is reserved. Reserved
15–8 LUT_PARAMETER_UPDATED_ADDR	The address of updated LUT parameter
7–0 LUT_PARAMETER_UPDATED_VALUE	The value of update LUT parameter

## 42.4.5 Display Normal Operation (SPDC\_OPERATE)

Address: 20E\_8000h base + 10h offset = 20E\_8010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	SW_TCON_RESET	Reserved														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved														DISP_RESET	DEEP_REFRESH
W																DISP_REFRESH
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

**SPDC\_OPERATE field descriptions**

Field	Description
31 SW_TCON_ RESET	Software TCON register reset When set to "1" it will trigger TCON start to reset all internal registers in TCON.
30–3 -	This field is reserved. Reserved
2 DISP_RESET	Display reset When set to "1" it will trigger TCON start to reset panel screen and automatic update next/current/previous frame memories according to flash LUT setting gray level.
1 DEEP_ REFRESH	Deep refresh (combine display reset and display refresh function) When set to "1" it will trigger TCON start to reset panel screen and automatic refresh panel screen base on DDR image data (current frame memory) with mode 0 waveform.
0 DISP_REFRESH	Display refresh When set to "1" it will trigger TCON start to refresh panel screen base on DDR image data (current frame memory) with mode 0 waveform.

**42.4.6 SPDC Initial Setting (SPDC\_PANEL\_INIT\_SET)****Table 42-12. Resolution Mapping Table of Gray Mode**

Resolution [4:0] (binary)	Resolution Setting (Width x Height)	Portrait / Landscape
11000	Display resolution is 600 x 800.	Portrait

## SPDC\_INT\_ST\_CLR field descriptions

Field	Description
31–4 -	This field is reserved. Reserved
3 TCON_ERROR_ INT_CLR	Error interrupt signal clear When set to "1" it will trigger TCON start to clear error interrupt.
2 LUT_ DOWNLOAD_ FINISH_INT_ CLR	LUT initial download finish interrupt signal clear When set to "1" it will trigger TCON start to clear LUT download finish interrupt.

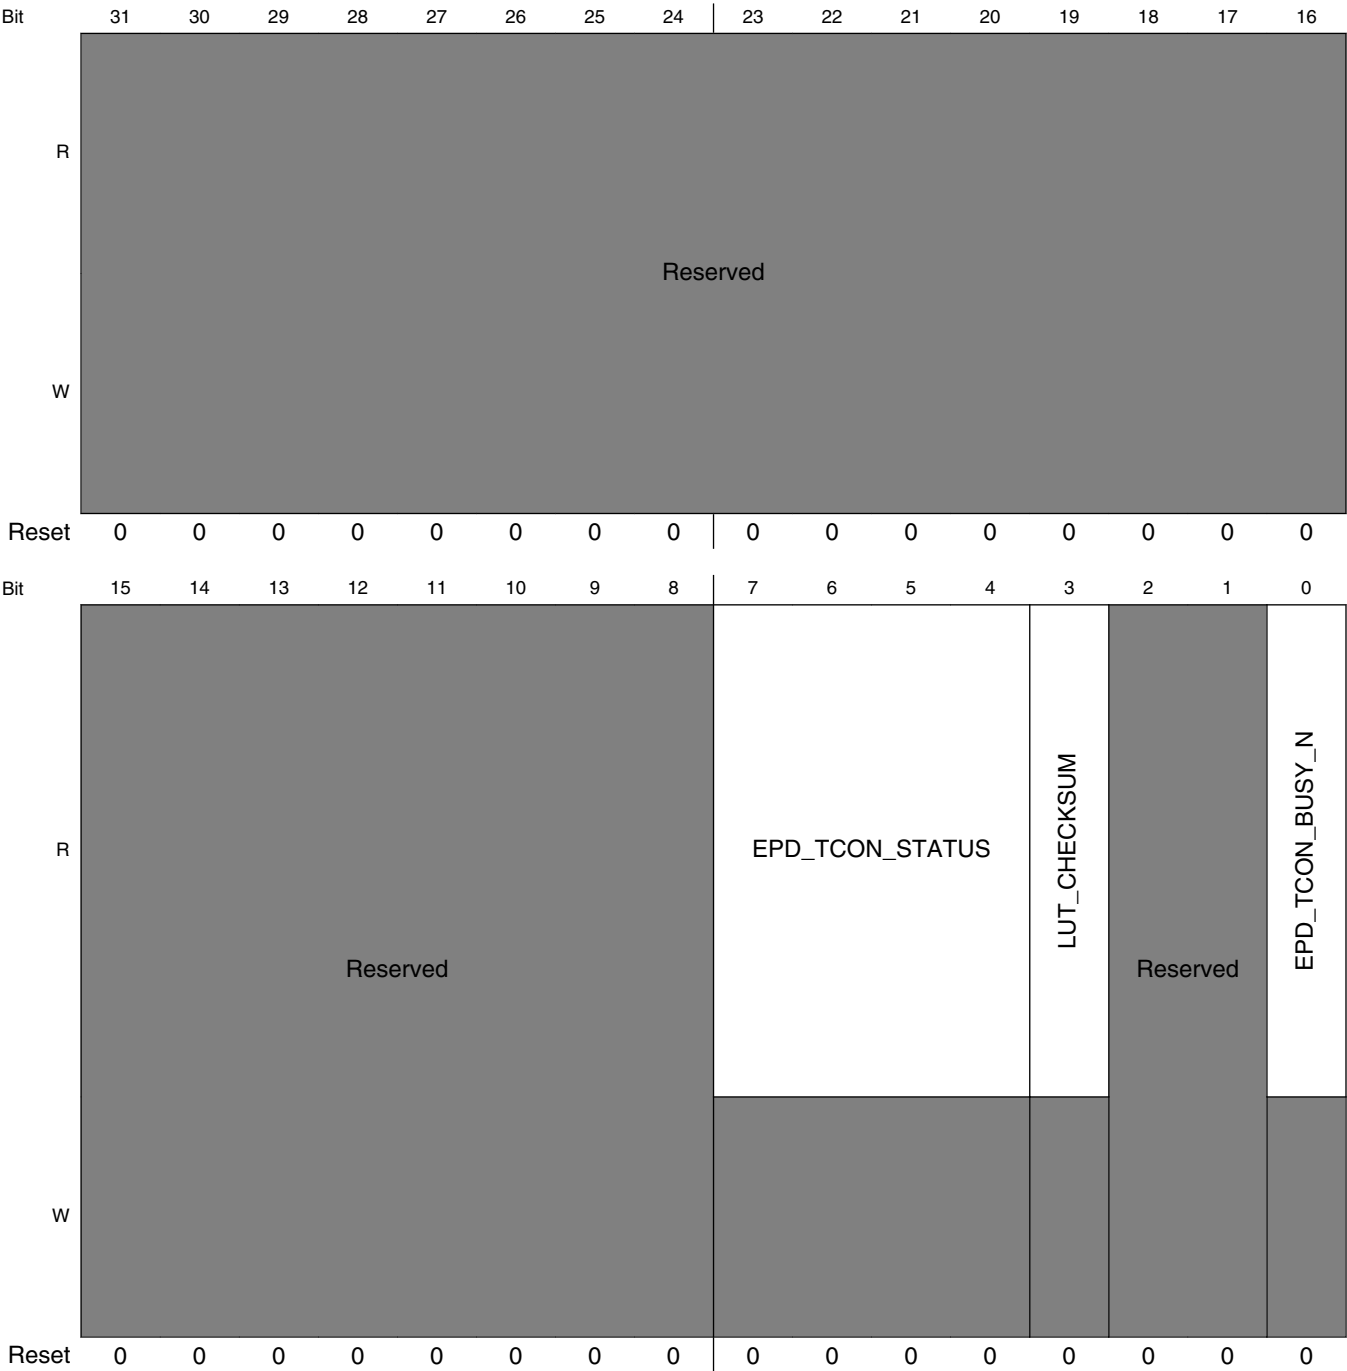

Table continues on the next page...

**SPDC\_INT\_ST\_CLR field descriptions (continued)**

<b>Field</b>	<b>Description</b>
1 TCON_INIT_ FINISH_INT_ CLR	TCON initialization finish interrupt signal clear When set to "1" it will trigger TCON start to clear TCON initialization finish interrupt.
0 UPDATE_ FINISH_INT_ CLR	Screen update finish interrupt signal clear When set to "1" it will trigger TCON start to clear screen update finish interrupt.

### 42.4.15 SPDC Operation Status (SPDC\_STATUS)

Address: 20E\_8000h base + 3Ch offset = 20E\_803Ch

**SPDC\_STATUS field descriptions**

Field	Description
31–8 -	This field is reserved. Reserved
7–4 EPD_TCON_ STATUS	EPD TCON IP status 0x0 RST_STATUS - EPD TCON during reset phase 0x1 WAIT_FOR_CHECKSUM_AND_POWER_READY_STATUS - EPD TCON is hold for waiting checksum pass and driver IC power ready 0x2 CHECKSUM_FAIL_BUT_POWER_READY_STATUS - EPD TCON checksum fail but driver IC power ready. User need reboot EPD TCON again and double check LUT correct or not. 0x3 INITIAL_WORKING_MEMORY_STATUS - EPD TCON automatic initial all working memories 0x4 IDLE_STATUS - EPD TCON idle status 0x7 MOVE_NEXT_TO_CURRENT_MEMORY_STATUS - EPD TCON automatic move next frame memory data to current frame memory. 0x9 LUT_UPDATE_STATUS - EPD TCON automatic update the waveform LUT 0xA PANEL_UPDATE_STATUS - EPD TCON is driving the panel screen.
3 LUT_ CHECKSUM	LUT checksum status 0x0 CHECKSUM_FAIL - LUT checksum fail 0x1 CHECKSUM_SUCCESS - LUT checksum pass
2–1 -	This field is reserved. Reserved
0 EPD_TCON_ BUSY_N	EPD TCON busy status 0x0 BUSY_STATUS - Panel is under updating 0x1 NOT_BUSY_STATUS - Panel update finished

## 42.4.16 Panel Type Related Information (SPDC\_PANEL\_TYPE\_VER)

Address: 20E\_8000h base + 40h offset = 20E\_8040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	EPD_PANEL_TYPE								LUT_VERSION								PRODUCT_AND_DRIVER_ID															
W

**SPDC\_PANEL\_TYPE\_VER field descriptions**

Field	Description
31–24 EPD_PANEL_ TYPE	EPD panel type, it stands for different material type of film. 0x0 ERK_1_4_A01 - Material type of film 0x1 ERK_1_4_D01 - Material type of film 0x2 ERK_2_0_A01 - Material type of film
